Abstract

Games on graphs provide the appropriate framework to study several central problems in computer science, such as the verification and synthesis of reactive systems. One of the most basic objectives for games on graphs is the liveness (or Büchi) objective that given a target set of vertices requires that some vertex in the target set is visited infinitely often. We study generalized Büchi objectives (i.e., conjunction of liveness objectives), and implications between two generalized Büchi objectives (known as GR(1) objectives), that arise in numerous applications in computer-aided verification. We present improved algorithms and conditional super-linear lower bounds based on widely believed assumptions about the complexity of (A1) combinatorial Boolean matrix multiplication and (A2) CNF-SAT. We consider graph games with n vertices, m edges, and generalized Büchi objectives with k conjunctions. First, we present an algorithm with running time $O(k \cdot n^2)$, improving the previously known $O(k \cdot n \cdot m)$ and $O(k^2 \cdot n^2)$ worst-case bounds. Our algorithm is optimal for dense graphs under (A1). Second, we show that the basic algorithm for the problem is optimal for sparse graphs when the target sets have constant size under (A2). Finally, we consider GR(1) objectives, with k_1 conjunctions in the antecedent and k_2 conjunctions in the consequent, and present an $O(k_1 \cdot k_2 \cdot n^{2.5})$ -time algorithm, improving the previously known $O(k_1 \cdot k_2 \cdot n \cdot m)$ -time algorithm for $m > n^{1.5}$.

1 Introduction

Games on graphs. Two-player games on graphs, between player 1 and the adversarial player 2, are central in many problems in computer science, especially in the formal analysis of reactive systems, where vertices of the graph represent states of the system, edges represent transitions, infinite paths of the graph represent behaviors (or non-terminating executions) of the system, and the two players represent the system and the environment, respectively. Games on graphs have been used in many applications related to the verification and synthesis of systems, such as, the synthesis of systems from specifications and controller-synthesis [Chu62, PR89, RW87], the verification of open systems [AHK02], checking interface compatibility [AH01], well-formedness of specifications [Dil89], and many others. We will distinguish between results most relevant for *sparse graphs*, where the number of edges m is roughly proportional to the number of vertices n , and *dense graphs* with $m = \Theta(n^2)$. Sparse graphs arise naturally

in program verification, as control-flow graphs are sparse [Tho98, CIP⁺15]. Graphs obtained as synchronous product of several components (where each component makes transitions at each step) [KP09, CGI⁺16] can lead to dense graphs.

Objectives. Objectives specify the desired set of behaviors of the system. The most basic objective for reactive systems is the *reachability* objective, and the next basic objective is the *Büchi* (also called *liveness* or *repeated reachability*) objective that was introduced in the seminal work of Büchi [Büc60, Büc62, BL69] for automata over infinite words. Büchi objectives are specified with a target set T and the objective specifies the set of infinite paths in the graph that visit some vertex in the target set infinitely often. Since for reactive systems there are multiple requirements, a very central objective to study for games on graphs is the conjunction of Büchi objectives, which is known as *generalized Büchi objective*. Finally, currently a very popular class of objectives to specify behaviors for reactive systems is called the *GR(1)* (*generalized reactivity (1)*) objectives [PPS06]. A GR(1) objective is an implication between two generalized Büchi objectives: the antecedent generalized Büchi objective is called the *assumption* and the consequent generalized Büchi objective is called the *guarantee*. In other words, the objective requires that if the assumption generalized Büchi objective is satisfied, then the guarantee generalized Büchi objective must also be satisfied.

We present a brief discussion about the significance of the objectives we consider, for a detailed discussion see [CH14]. The conjunction of Büchi objectives is required to specify progress conditions of mutual exclusion protocols, and deterministic Büchi automata can express many important properties of linear-time temporal logic (LTL) (the de-facto logic to specify properties of reactive systems) [KV05, KV98, AT04, KPB94]. The analysis of reactive systems with such objectives naturally gives rise to graph games with generalized Büchi objectives. Finally, graph games with GR(1) objectives have been used in many applications, such as the industrial example of synthesis of AMBA AHB protocol [BGJ⁺07, GCH11] as well as in robotics applications [FKP05, CCG⁺15].

Basic problem and conditional lower bounds. In this work we consider games on graphs with generalized Büchi and GR(1) objectives, and the basic algorithmic problem is to compute the *winning set*, i.e., the set of starting vertices where player 1 can ensure the objective irrespective of the way player 2 plays; the way player 1 achieves this is called her *winning strategy*. These are core algorithmic problems in verification and synthesis. For the problems we consider, while polynomial-time algorithms are known, there are no super-linear lower bounds. Since for polynomial-time algorithms unconditional super-linear lower bounds are extremely rare in the whole of computer science, we consider *conditional lower bounds*, which assume that for some well-studied problem the known algorithms are optimal up to some lower-order factors. In this work we consider two such well-studied assumptions: (A1) there is no combinatorial¹ algorithm with running time of $O(n^{3-\varepsilon})$ for any $\varepsilon > 0$ to multiply two $n \times n$ Boolean matrices; or (A2) for all $\varepsilon > 0$ there exists a k such that there is no algorithm for the k -CNF-SAT problem that runs in $O(2^{(1-\varepsilon) \cdot n} \cdot \text{poly}(m))$ time, where n is the number of variables and m the number of clauses. These two assumptions have been used to establish lower bounds for several well-studied problems, such as dynamic graph algorithms [AVW14, AVWY15], measuring the similarity of strings [AVWW14, Bri14, BK15, BI15, ABVW15b], context-free grammar parsing [Lee02, ABVW15a], and verifying

¹Combinatorial here means avoiding fast matrix multiplication [LG14], see also the discussion in [HKN⁺15].

first-order graph properties [PW10, Wil14b].

Our results. We consider games on graphs with n vertices, m edges, generalized Büchi objectives with k conjunctions, and target sets of size b_1, b_2, \dots, b_k , and GR(1) objectives with k_1 conjunctions in the assumptions and k_2 conjunctions in the guarantee. Our results are as follows.

- *Generalized Büchi objectives.* The classical algorithm for generalized Büchi objectives requires $O(k \cdot \min_{1 \leq i \leq k} b_i \cdot m)$ time. Furthermore, there exists an $O(k^2 \cdot n^2)$ -time algorithm via a reduction to Büchi games [BCG⁺10, CH14].
 1. *Dense graphs.* Since $\min_{1 \leq i \leq k} b_i = O(n)$ and $m = O(n^2)$, the classical algorithm has a worst-case running time of $O(k \cdot n^3)$. First, we present an algorithm with worst-case running time $O(k \cdot n^2)$, which is an improvement for instances with $\min_{1 \leq i \leq k} b_i \cdot m = \omega(n^2)$. Second, for dense graphs with $m = \Theta(n^2)$ and $k = \Theta(n^c)$ for any $0 < c \leq 1$ our algorithm is optimal under (A1); i.e., improving our algorithm for dense graphs would imply a faster (sub-cubic) combinatorial Boolean matrix multiplication algorithm.
 2. *Sparse graphs.* We show that for $k = \Theta(n^c)$ for any $0 < c \leq 1$, for target sets of constant size, and sparse graphs with $m = \Theta(n^{1+o(1)})$ the basic algorithm is optimal under (A2). In fact, our conditional lower bound under (A2) holds even when each target set is a singleton. Quite strikingly, our result implies that improving the basic algorithm for sparse graphs even with singleton sets would require a major breakthrough in overcoming the exponential barrier for SAT.

In summary, for games on graphs, we present an improved algorithm for generalized Büchi objectives for dense graphs that is optimal under (A1); and show that under (A2) the basic algorithm is optimal for sparse graphs and constant size target sets.

The conditional lower bound for dense graphs means in particular that for unrestricted inputs the dependence of the runtime on n cannot be improved, whereas the bound for sparse graphs makes the same statement for the dependence on m . Moreover, as the graphs in the reductions for our lower bounds can be made acyclic by deleting a single vertex, our lower bounds also apply to a broad range of digraph parameters. For instance, let w be the DAG-width [BDH⁺06] of a graph, then there is no $O(f(w) \cdot n^{3-o(1)})$ -time algorithm under (A1) and no $O(f(w) \cdot m^{2-o(1)})$ -time algorithm under (A2).

- *GR(1) objectives.* We present an algorithm for games on graphs with GR(1) objectives that has $O(k_1 \cdot k_2 \cdot n^{2.5})$ running time and improves the previously known $O(k_1 \cdot k_2 \cdot n \cdot m)$ -time algorithm [JP06] for $m > n^{1.5}$. Note that since generalized Büchi objectives are special cases of GR(1) objectives, our conditional lower bounds for generalized Büchi objectives apply to GR(1) objectives as well, but are not tight.

All our algorithms can easily be modified to also return the corresponding winning strategies for both players within the same time bounds.

Implications. We discuss the implications of our results.

1. *Comparison with related models.* We compare our results for game graphs to the special case of standard graphs (i.e., games on graphs with only player 1) and the

related model of Markov decision processes (MDPs) (with only player 1 and stochastic transitions). First note that for reachability objectives, linear-time algorithms exist for game graphs [Bee80, Imm81], whereas for MDPs² the best-known algorithm has running time $O(\min(n^2, m^{1.5}))$ [CJH03, CH14]. For MDPs with reachability objectives, a linear or even $O(m \log n)$ time algorithm is a major open problem, i.e., there exist problems that seem harder for MDPs than for game graphs. Our conditional lower bound results show that under assumptions (A1) and (A2) the algorithmic problem for generalized Büchi objectives is strictly harder for games on graphs as compared to standard graphs and MDPs. More concretely, for $k = \Theta(n)$, (a) for dense graphs ($m = \Theta(n^2)$) and $\min_{1 \leq i \leq k} b_i = \Omega(\log n)$, our lower bound for games on graphs under (A2) is $\Omega(n^{3-o(1)})$, whereas both the graph and the MDP problems can be solved in $O(n^2)$ time [CH12, CH14]; and (b) for sparse graphs ($m = \Theta(n^{1+o(1)})$) with $\min_{1 \leq i \leq k} b_i = O(1)$, our lower bound for games on graphs under (A1) is $\Omega(m^{2-o(1)})$, whereas the graph problem can be solved in $O(m)$ time and the MDP problem in $O(m^{1.5})$ time [AH04, CH11]; respectively.

2. *Relation to SAT.* We present an algorithm for game graphs with generalized Büchi objectives and show that improving the algorithm would imply a better algorithm for SAT, and thereby establish an interesting algorithmic connection for classical objectives in game graphs and the SAT problem.

Outline. In Section 2 we provide formal definitions and state the conjectures on which the conditional lower bounds are based. In Section 3 we consider algorithms for generalized Büchi objectives and first present a basic algorithm which is in $O(knm)$ time and then improve it to an $O(k \cdot n^2)$ -time algorithm. In Section 4 we provide conditional lower bounds for generalized Büchi objectives. Finally, in Section 5 we study algorithms for games with GR(1) objective and first give a basic algorithm which is in $O(k_1 \cdot k_2 \cdot n^3)$ time and then improve it to an $O(k_1 \cdot k_2 \cdot n^{2.5})$ -time algorithm.

2 Preliminaries

2.1 Basic definitions for Games on Graphs

Game graphs. A *game graph* $\mathcal{G} = ((V, E), (V_1, V_2))$ is a directed graph $G = (V, E)$ with a set of vertices V and a set of edges E and a partition of V into *player 1 vertices* V_1 and *player 2 vertices* V_2 . Let $n = |V|$ and $m = |E|$. Given such a game graph \mathcal{G} , we denote with $\bar{\mathcal{G}}$ the game graph where the player 1 and player 2 vertices of \mathcal{G} are interchanged, i.e., $\bar{\mathcal{G}} = ((V, E), (V_2, V_1))$. We use p to denote a player and \bar{p} to denote its opponent. For a vertex $u \in V$, we write $Out(u) = \{v \in V \mid (u, v) \in E\}$ for the set of successor vertices of u and $In(u) = \{v \in V \mid (v, u) \in E\}$ for the set of predecessor vertices of u . If necessary, we refer to the successor vertices in a specific graph by using, e.g., $Out(G, u)$. We denote by $Outdeg(u) = |Out(u)|$ the number of outgoing edges from u , and by $Indeg(u) = |In(u)|$ the number of incoming edges. We assume for technical convenience $Outdeg(u) \geq 1$ for all $u \in V$.

²For MDPs the winning set refers to the almost-sure winning set that requires that the objective is satisfied with probability 1.

Plays and strategies. A *play* on a game graph is an infinite sequence $\omega = \langle v_0, v_1, v_2, \dots \rangle$ of vertices such that $(v_\ell, v_{\ell+1}) \in E$ for all $\ell \geq 0$. The set of all plays is denoted by Ω . Given a finite prefix $\omega \in V^* \cdot V_p$ of a play that ends at a player p vertex v , a *strategy* $\sigma : V^* \cdot V_p \rightarrow V$ of player p is a function that chooses a successor vertex $\sigma(\omega)$ among the vertices of $Out(v)$. We denote by Σ and Π the set of all strategies of player 1 and player 2 respectively. The play $\omega(v, \sigma, \pi)$ is uniquely defined by a start vertex v , a player 1 strategy $\sigma \in \Sigma$, and a player 2 strategy $\pi \in \Pi$ as follows: $v_0 = v$ and for all $j \geq 0$, if $v_j \in V_1$, then $v_{j+1} = \sigma(\langle v_1, \dots, v_j \rangle)$, and if $v_j \in V_2$, then $v_{j+1} = \pi(\langle v_1, \dots, v_j \rangle)$.

Objectives. An objective ψ is a set of plays that is winning for a player. We consider zero-sum games where for a player-1 objective ψ the complementary objective $\Omega \setminus \psi$ is winning for player 2. In this work we consider only *prefix independent objectives*, for which the set of desired plays is determined by the set of vertices $\text{Inf}(\omega)$ that occur *infinitely often* in a play ω . Given a target set $T \subseteq V$, a play ω belongs to the *Büchi objective* $\text{Büchi}(T)$ iff $\text{Inf}(\omega) \cap T \neq \emptyset$. For the complementary *co-Büchi objective* we have $\omega \in \text{coBüchi}(T)$ iff $\text{Inf}(\omega) \cap T = \emptyset$. A *generalized (or conjunctive) Büchi objective* is specified by a set of k target sets T_ℓ for $1 \leq \ell \leq k$ and is satisfied for a play ω iff $\text{Inf}(\omega) \cap T_\ell \neq \emptyset$ for *all* $1 \leq \ell \leq k$. Its complementary objective is the *disjunctive co-Büchi objective* that is satisfied iff $\text{Inf}(\omega) \cap T_\ell = \emptyset$ for *one of* the k target sets. A *generalized reactivity-1 (GR(1)) objective* is specified by two generalized Büchi objectives, $\bigwedge_{t=1}^{k_1} \text{Büchi}(L_t)$ and $\bigwedge_{\ell=1}^{k_2} \text{Büchi}(U_\ell)$, and is satisfied if whenever the first generalized Büchi objective holds, then also the second generalized Büchi objective holds; in other words, either $\bigvee_{t=1}^{k_1} \text{coBüchi}(L_t)$ holds, or $\bigwedge_{\ell=1}^{k_2} \text{Büchi}(U_\ell)$ holds.

In this paper we specify a game by a game graph \mathcal{G} and an objective ψ for player 1. Player 2 has the complementary objective $\Omega \setminus \psi$.

Winning strategies and sets. A strategy σ is winning for player p at a start vertex v if the resulting play is winning for player p irrespective of the strategy of his opponent, player \bar{p} , i.e., $\omega(v, \sigma, \pi) \in \psi$ for all π . A vertex v belongs to the *winning set* W_p of player p if player p has a winning strategy from v . Every vertex is winning for exactly one of the two players [Mar75] (cf. Theorem 2.1). When an explicit reference to a specific game (\mathcal{G}, ψ) is required, we use $W_p(\mathcal{G}, \psi)$ to refer to the winning sets.

Theorem 2.1 ([Mar75]). *In graph games with prefix independent objectives the winning sets of the two players partition the vertex set V .*

For the analysis of our algorithms we further introduce the notions of *closed sets*, *attractors*, and *dominions*.

Closed sets. A set $U \subseteq V$ is *p-closed* (in \mathcal{G}) if for all p -vertices u in U we have $Out(u) \subseteq U$ and for all \bar{p} -vertices v in U there exists a vertex $w \in Out(v) \cap U$. Note that player \bar{p} can ensure that a play that currently ends in a p -closed set never leaves the p -closed set against any strategy of player p by choosing an edge (v, w) with $w \in Out(v) \cap U$ whenever the current vertex v is in $U \cap V_{\bar{p}}$ [Zie98]. Given a game graph \mathcal{G} and a p -closed set U , we denote by $\mathcal{G}[U]$ the game graph induced by the set of vertices U . Note that given that in \mathcal{G} each vertex has at least one outgoing edge, the same property holds for $\mathcal{G}[U]$. We further use the shortcut $\mathcal{G} \setminus X$ to denote $\mathcal{G}[V \setminus X]$.

Attractors. In a game graph \mathcal{G} , a *p-attractor* $\text{Attr}_p(\mathcal{G}, U)$ of a set $U \subseteq V$ is the set of vertices from which player p has a strategy to reach U against all strategies of player \bar{p} [Zie98]. We

have that $U \subseteq \text{Attr}_p(\mathcal{G}, U)$. A p -attractor can be constructed inductively as follows: Let $R_0 = U$; and for all $j \geq 0$ let

$$R_{j+1} = R_j \cup \{v \in V_p \mid \text{Out}(v) \cap R_j \neq \emptyset\} \cup \{v \in V_{\bar{p}} \mid \text{Out}(v) \subseteq R_j\}.$$

Then $\text{Attr}_p(\mathcal{G}, U) = \bigcup_{j \geq 0} R_j$.

The p -rank of a vertex v w.r.t. a set U is given by $\text{rank}_p(\mathcal{G}, U, v) = \min\{j \mid v \in R_j\}$ if $v \in \text{Attr}_p(\mathcal{G}, U)$ and is ∞ otherwise.

Dominions. A set of vertices $D \neq \emptyset$ is a player- p *dominion* if player p has a winning strategy from every vertex in D that also ensures only vertices in D are visited. The notion of dominions was introduced by [JPZ08]. Note that a player- p dominion is also a \bar{p} -closed set and the p -attractor of a player- p dominion is again a player- p dominion.

The lemma below summarizes some well-known facts about closed sets, attractors, and winning sets.

Lemma 2.2. *The following assertions hold for game graphs \mathcal{G} where each vertex has at least one outgoing edge. The assertions referring to winning sets hold for graph games with prefix independent objectives. Let $X \subseteq V$.*

1. *From each vertex of $\text{Attr}_p(\mathcal{G}, X)$ player p has a memoryless strategy that stays within $\text{Attr}_p(\mathcal{G}, X)$ to reach X against any strategy of player \bar{p} [Zie98].*
2. *The attractor $\text{Attr}_p(\mathcal{G}, X)$ can be computed in $O(\sum_{v \in \text{Attr}_p(\mathcal{G}, X)} |\text{In}(v)|)$ time [Bee80, Imm81].*
3. *The set $V \setminus \text{Attr}_p(\mathcal{G}, X)$ is p -closed on \mathcal{G} [Zie98, Lemma 4].*
4. *Let X be p -closed on \mathcal{G} . Then $W_{\bar{p}}(\mathcal{G}[X]) \subseteq W_{\bar{p}}(\mathcal{G})$ [JPZ08, Lemma 4.4].*
5. *Let X be a subset of the winning set $W_p(\mathcal{G})$ of player p and let A be its p -attractor $\text{Attr}_p(\mathcal{G}, X)$. Then the winning set $W_p(\mathcal{G})$ of the player p is the union of A and the winning set $W_p(\mathcal{G}[V \setminus A])$, and the winning set $W_{\bar{p}}(\mathcal{G})$ of the opponent \bar{p} is equal to $W_{\bar{p}}(\mathcal{G}[V \setminus A])$ [JPZ08, Lemma 4.5].*

2.2 Conjectured Lower Bounds

While classical complexity results are based on assumptions about relationships between complexity classes, e.g., $P \neq NP$, polynomial lower bounds are often based on widely believed, conjectured lower bounds for well studied algorithmic problems. We next discuss the popular conjectures that will be the basis for our lower bounds for generalized Büchi games.

First, we consider conjectures on Boolean matrix multiplication [VWW10, AVW14] and triangle detection [AVW14] in graphs, which build the basis for our lower bounds on dense graphs. A triangle in a graph is a triple x, y, z of distinct vertices such that $(x, y), (y, z), (z, x) \in E$.

Conjecture 2.3 (Combinatorial Boolean Matrix Multiplication Conjecture (BMM)). *There is no $O(n^{3-\varepsilon})$ time combinatorial algorithm for computing the Boolean product of two $n \times n$ matrices for any $\varepsilon > 0$.*

Conjecture 2.4 (Strong Triangle Conjecture (STC)). *There is no $O(\min\{n^{\omega-\varepsilon}, m^{2\omega/(\omega+1)-\varepsilon}\})$ expected time algorithm and no $O(n^{3-\varepsilon})$ time combinatorial algorithm that can detect whether a graph contains a triangle for any $\varepsilon > 0$, where $\omega < 2.373$ is the matrix multiplication exponent.*

By a result of Vassilevska Williams and Williams [VWW10], we have that BMM is equivalent to the combinatorial part of STC. Moreover, if we do not restrict ourselves to combinatorial algorithms, STC still gives a super-linear lower bound.

Second, we consider the Strong Exponential Time Hypothesis [IPZ01, CIP09] and the Orthogonal Vectors Conjecture [AWW16], the former dealing with satisfiability in propositional logic and the latter with the *Orthogonal Vectors Problem*.

The Orthogonal Vectors Problem (OV). Given two sets S_1, S_2 of d -bit vectors with $|S_1|, |S_2| \leq N$ and $d \in \Theta(\log N)$, are there $u \in S_1$ and $v \in S_2$ such that $\sum_{i=1}^d u_i \cdot v_i = 0$?

Conjecture 2.5 (Strong Exponential Time Hypothesis (SETH)). *For each $\varepsilon > 0$ there is a k such that k -CNF-SAT on n variables and m clauses cannot be solved in time $O(2^{(1-\varepsilon)n} \text{poly}(m))$.*

Conjecture 2.6 (Orthogonal Vectors Conjecture (OVC)). *There is no $O(N^{2-\varepsilon})$ time algorithm for the Orthogonal Vectors Problem for any $\varepsilon > 0$.*

By a result of Williams [Wil05] we know that SETH implies OVC, i.e., whenever a problem is hard assuming OVC, it is also hard when assuming SETH. Hence, it is preferable to use OVC for proving lower bounds. Finally, to the best of our knowledge, no such relations between the former two conjectures and the latter two conjectures are known.

Remark 2.7. *The conjectures that no polynomial improvements over the best known running times are possible do not exclude improvements by sub-polynomial factors such as polylogarithmic factors or factors of, e.g., $2^{\sqrt{\log n}}$ as in [Wil14a].*

3 Algorithms for Generalized Büchi Games

For generalized Büchi games we first present the basic algorithm that follows from the results of [EJ91, McN93, Zie98]. The basic algorithm (cf. Algorithm **GENBUCHIGAMEBASIC**) runs in time $O(knm)$. We then improve it to an $O(k \cdot n^2)$ -time algorithm by exploiting ideas from the $O(n^2)$ -time algorithm for Büchi games in [CH12]. The basic algorithm is fast for instances where one Büchi set is small, i.e., the algorithm runs in time $O(k \cdot \min_{1 \leq \ell \leq k} b_\ell \cdot m)$ time, where $b_\ell = |T_\ell|$.

Reduction to Büchi Games. Another way to implement generalized Büchi games is by a reduction to Büchi games as follows (see also [BCG⁺10]). Make k copies V^ℓ , $1 \leq \ell \leq k$, of the vertices of the original game graph and draw an edge (v^j, u^j) if (v, u) is an edge in the original graph and $v \notin T_j$, and an edge $(v^j, u^{j \oplus 1})$ if (v, u) is an edge in the original graph and $v \in T_j$ (where $j \oplus 1 = j + 1$ for $j < k$ and $k \oplus 1 = 1$). Finally, pick the Büchi set T_ℓ of minimal size and make its copy T_ℓ^ℓ in V^ℓ the target set for the Büchi game. This reduction results in another $O(k \cdot \min_{1 \leq \ell \leq k} b_\ell \cdot m)$ time algorithm when combined with the basic algorithm for Büchi and in an $O(k^2 n^2)$ time algorithm when combined with the $O(n^2)$ time algorithm for Büchi [CH12].

Notation. Our algorithms iteratively identify sets of vertices that are winning for player 2, i.e., player-2 dominions, and remove them from the graph. In the algorithms and their analysis we denote the sets in the j th-iteration with superscript j , in particular $\mathcal{G}^1 = \mathcal{G}$, where \mathcal{G} is the input game graph, G^j is the graph of \mathcal{G}^j , V^j is the vertex set of G^j , and $T_\ell^j = V^j \cap T_\ell$. We also use $\{T_\ell^j\}$ to denote the list of Büchi sets $(T_1^j, T_2^j, \dots, T_k^j)$, in particular when updating all the sets in a uniform way.

3.1 Basic Algorithm

For each set U that is closed for player 1 we have that from each vertex $u \in U$ player 2 has a strategy to ensure that the play never leaves U [Zie98]. Thus, if there is a Büchi set T_ℓ with $T_\ell \cap U = \emptyset$, then the set U is a player-2 dominion. Moreover, if U is a player-2 dominion, also the attractor $\text{Attr}_2(\mathcal{G}, U)$ of U is a player-2 dominion. The basic algorithm (cf. Algorithm **GENBUCHIGAMEBASIC**) proceeds as follows. It iteratively computes vertex sets S^j closed for player 1 that do not intersect with one of the Büchi sets. If such a player-2 dominion S^j is found, then all vertices of $\text{Attr}_2(\mathcal{G}^j, S^j)$ are marked as winning for player 2 and removed from the game graph; the remaining game graph is denoted by \mathcal{G}^{j+1} . To find a player-2 dominion S^j , for each $1 \leq \ell \leq k$ the attractor $Y_\ell^j = \text{Attr}_1(\mathcal{G}^j, T_\ell^j)$ of the Büchi set T_ℓ^j is determined. If for some ℓ the complement of Y_ℓ^j is not empty, then we assign $S^j = V^j \setminus Y_\ell^j$ for the smallest such ℓ . The algorithm terminates if in some iteration j for each $1 \leq \ell \leq k$ the attractor Y_ℓ^j contains all vertices of V^j . In this case the set V^j is returned as the winning set of player 1. The winning strategy of player 1 from these vertices is then a combination of the attractor strategies to the sets T_ℓ^j .

Algorithm GENBUCHIGAMEBASIC: Generalized Büchi Games in $O(k \cdot b_1 \cdot m)$ Time

Input : Game graph $\mathcal{G} = ((V, E), (V_1, V_2))$ and objective $\bigwedge_{1 \leq \ell \leq k} \text{Büchi}(T_\ell)$

Output: Winning set of player 1

```

1  $\mathcal{G}^1 \leftarrow \mathcal{G}$ 
2  $\{T_\ell^1\} \leftarrow \{T_\ell\}$ 
3  $j \leftarrow 0$ 
4 repeat
5    $j \leftarrow j + 1$ 
6   for  $1 \leq \ell \leq k$  do
7      $Y_\ell^j \leftarrow \text{Attr}_1(\mathcal{G}^j, T_\ell^j)$ 
8      $S^j \leftarrow V^j \setminus Y_\ell^j$ 
9     if  $S^j \neq \emptyset$  then break
10   $D^j \leftarrow \text{Attr}_2(\mathcal{G}^j, S^j)$ 
11   $\mathcal{G}^{j+1} \leftarrow \mathcal{G}^j \setminus D^j$ 
12   $\{T_\ell^{j+1}\} \leftarrow \{T_\ell^j \setminus D^j\}$ 
13 until  $D^j = \emptyset$ 
14 return  $V^j$ 

```

Proposition 3.1 (Runtime Algorithm **GENBUCHIGAMEBASIC**). *The basic algorithm for generalized Büchi games terminates in $O(k \cdot b_1 \cdot m)$ time, where $b_1 = |T_1|$, and thus also in $O(knm)$ time.*

Proof. In each iteration of the repeat-until loop at most $k + 1$ attractor computations are performed, which can each be done in $O(m)$ time. We next argue that the repeat-until loop terminates after at most $2b_1 + 2$ iterations. We use that (a) a player-2 edge from $Y_\ell^j = \text{Attr}_1(\mathcal{G}^j, T_\ell^j)$ to $V^j \setminus Y_\ell^j$ has to originate from a vertex of T_ℓ^j and (b) if a player-1

attractor contains a vertex, then it contains also the player-1 attractor of this vertex. In each iteration we have one of the following situations:

1. $S^j = \emptyset$: The algorithm terminates.
2. $\text{Attr}_1(\mathcal{G}^j, T_1^j) = V^j$ and $\text{Attr}_1(\mathcal{G}^j, T_\ell^j) \neq V^j$ for some $\ell > 1$: We have that $T_1^j \not\subseteq \text{Attr}_1(\mathcal{G}^j, T_\ell^j)$ as $T_1^j \subseteq \text{Attr}_1(\mathcal{G}^j, T_\ell^j)$ would imply that also $\text{Attr}_1(\mathcal{G}^j, T_1^j) = V^j \subseteq \text{Attr}_1(\mathcal{G}^j, T_\ell^j)$ which is in contradiction to the assumption. Thus we obtain $|T_1^{j+1}| < |T_1^j|$.
3. $\text{Attr}_1(\mathcal{G}^j, T_1^j) \neq V^j$ and $D^j \cap T_1^j \neq \emptyset$: We immediately get $|T_1^{j+1}| < |T_1^j|$.
4. $\text{Attr}_1(\mathcal{G}^j, T_1^j) \neq V^j$ and $D^j \cap T_1^j = \emptyset$: In this case $D^j = \text{Attr}_2(\mathcal{G}^j, S^j) = S^j$ and thus in the next iteration we have either situation (1) or (2). Notice that, for each vertex $v \in \text{Attr}_1(\mathcal{G}^j, T_1^j)$ player 1 has a strategy to reach T_1^j and thus for v to be in D^j the set D^j has to contain at least one vertex of T_1^j .

By the above we have that T_1^j is decreased in at least every second iteration of the loop. For $T_1^j = \emptyset$ we have $\text{Attr}_1(\mathcal{G}^j, T_1^j) = \emptyset$ and thus $V^{j+1} = \emptyset$, which terminates the algorithm in the next iteration. Thus we have that each iteration takes time $O(km)$ and there are $2b_1 + 2$, i.e., $O(b_1)$, iterations. \square

As we can always rearrange the Büchi sets such that $b_1 = \min_{1 \leq \ell \leq k} b_\ell$ this gives an $O(k \cdot \min_{1 \leq \ell \leq k} b_\ell \cdot m)$ algorithm for generalized Büchi games.

For the final game graph \mathcal{G}^j we have that all vertices are in all the player-1 attractors of Büchi sets T_ℓ . Thus player 1 can win the game by following one attractor strategy until the corresponding Büchi set is reached and then switching to the attractor strategy of the next Büchi set.

Proposition 3.2 (Soundness Algorithm **GENBUCHIGAMEBASIC**). *Let V^{j*} be the set of vertices returned by the algorithm. Each vertex in V^{j*} is winning for player 1.*

Proof. Let the j^* -th iteration be the last iteration of the algorithm. We have $S^{j*} = \emptyset$. Thus each vertex of V^{j*} is contained in $\text{Attr}_1(\mathcal{G}^{j*}, T_\ell^{j*})$ for each $1 \leq \ell \leq k$. Additionally, either $V^{j*} = \emptyset$ or $T_\ell^{j*} \neq \emptyset$ for all $1 \leq \ell \leq k$. Further we have that V^{j*} is closed for player 2 as only player 2 attractors were removed from V to obtain V^{j*} (i.e., we apply Lemma 2.2(3) inductively). Hence player 1 has the following winning strategy (with memory) on the vertices of V^{j*} : On the vertices of $V^{j*} \setminus \bigcap_{\ell=1}^k T_\ell^{j*}$ first follow the attractor strategy (Lemma 2.2(1)) for T_1^{j*} until a vertex of T_1^{j*} is reached, then the attractor strategy for T_2^{j*} until a vertex of T_2^{j*} is reached and so on until the set T_k^{j*} is reached; then restart with T_1^{j*} . On the vertices of $\bigcap_{\ell=1}^k T_\ell^{j*} \cap V_1$ player 1 can pick any outgoing edge whose endpoint is in V^{j*} . Since V^{j*} is closed for player 2 and $T_\ell^{j*} \neq \emptyset$ for all $1 \leq \ell \leq k$, this strategy exists, never leaves the set V^{j*} , and satisfies the generalized Büchi objective. \square

For completeness we use that each 1-closed set that avoids one Büchi set is winning for player 2 and that, by Lemma 2.2(5), we can remove such sets from the game graph.

Proposition 3.3 (Completeness Algorithm **GENBUCHIGAMEBASIC**). *Let V^{j*} be the set returned by the algorithm. Player 2 has a winning strategy from each vertex in $V \setminus V^{j*}$.*

Figure 1: Illustration of the hierarchical graph decomposition. Circles denote player 1 vertices, squares denote player 2 vertices. In the original graph G all the edges (solid, dashed, dotted) are present. From the hierarchical graph decomposition we consider the graphs G_1 , G_2 and G_3 . G_1 contains only the solid edges, G_2 additionally the dashed edges, and G_3 also contains the dotted edge, i.e., $G = G_3$. Let the target sets be $T_1 = \{a, e, i\}$ and $T_2 = \{b, d\}$. Then the set $\{e, j\}$ is a player-2 dominion of G that can be detected in G_1 . Its player-2 attractor contains additionally the vertex d . To detect that the remaining vertices are winning for player 1 it is necessary to consider the dotted edge.

Proof. By Lemma 2.2(5) it is sufficient to show that, in each iteration j , player 2 has a winning strategy in \mathcal{G}^j from each vertex of S^j . Let ℓ be such that $S^j = V^j \setminus Attr_1(\mathcal{G}^j, T_\ell^j)$. By Lemma 2.2(3) the set S^j is closed for player 1 in \mathcal{G}^j , that is, player 2 has a strategy that keeps the play within $\mathcal{G}^j[S^j]$ against any strategy of player 1. Since $S^j \cap T_\ell^j = \emptyset$, this strategy is winning for player 2 (i.e., it satisfies $\text{coBuchi}(T_\ell^j)$ and thus the disjunctive co-Büchi objective). \square

3.2 Our Improved Algorithm

The $O(k \cdot n^2)$ -time Algorithm **GENBUCHIGAME** for generalized Büchi games combines the basic algorithm for generalized Büchi games described above with the method used for the $O(n^2)$ -time Büchi game algorithm [CH14], called *hierarchical graph decomposition* [HKW99]. The hierarchical graph decomposition defines for a directed graph $G = (V, E)$ and integers $1 \leq i \leq \lceil \log_2 n \rceil$ the graphs $G_i = (V, E_i)$. Assume the incoming edges of each vertex in G are given in some fixed order in which first the edges from vertices of V_2 and then the edges from vertices of V_1 are listed. The set of edges E_i contains all the outgoing edges of each $v \in V$ with $\text{Outdeg}(G, v) \leq 2^i$ and the first 2^i incoming edges of each vertex. Note that $G = G_{\lceil \log_2 n \rceil}$ and $|E_i| \in O(n \cdot 2^i)$. See Figure 1 for an example. The runtime analysis uses that we can identify small player-2 dominions (i.e., player-1 closed sets that do not intersect one of the target sets) that contain $O(2^i)$ vertices by considering only G_i . The algorithm first searches for such a set S^j in G_i for $i = 1$ and each target set and then increases i until the search is successful. In this way the time spent for the search is proportional to $k \cdot n$ times the number of vertices in the found dominion, which yields a total runtime bound of $O(k \cdot n^2)$. To obtain the $O(k \cdot n^2)$ running time bound, it is crucial to put the loop over the different Büchi sets as the innermost part of the algorithm. Given a game graph $\mathcal{G} = (G, (V_1, V_2))$, we denote by \mathcal{G}_i the game graph where G was replaced by G_i from the hierarchical graph decomposition, i.e., $\mathcal{G}_i = (G_i, (V_1, V_2))$.

Properties of hierarchical graph decomposition. The essential properties of the hierarchical graph decomposition for (generalized) Büchi games are summarized in the following lemma. The first part is crucial for correctness: When searching in G_i for a player 1 closed set that

Algorithm GENBUCHIGAME: Generalized Büchi Games in $O(k \cdot n^2)$ Time

17 return  $V^j$ 

```

does not contain one of the target sets, we can ensure that such a set is also closed for player 1 in G by excluding certain vertices that are missing outgoing edges in G_i from the search. The second part is crucial for the runtime argument: Whenever the basic algorithm would remove (i.e., identify as winning for player 2) a set of vertices with at most 2^i vertices, then we can identify this set also by searching in G_i instead of G . The vertices Z_i we exclude for the search on G_i are player-1 vertices with more than 2^i outgoing edges and player-2 vertices with no outgoing edges in G_i . Note that the latter can only happen if $\text{Outdeg}(G, v) > 2^i$.

Lemma 3.4. *Let $\mathcal{G} = (G = (V, E), (V_1, V_2))$ be a game graph and $\{G_i\}$ its hierarchical graph decomposition. For $1 \leq i \leq \lceil \log_2 n \rceil$ let Z_i be the set consisting of the player 2 vertices that have no outgoing edge in G_i and the player 1 vertices with $> 2^i$ outgoing edges in \mathcal{G} .*

1. *If a set $S \subseteq V \setminus Z_i$ is closed for player 1 in \mathcal{G}_i , then S is closed for player 1 in \mathcal{G} .*
2. *If a set $S \subseteq V$ is closed for player 1 in \mathcal{G} and $|\text{Attr}_2(\mathcal{G}, S)| \leq 2^i$, then (i) $\mathcal{G}_i[S] = \mathcal{G}[S]$, (ii) the set S is in $V \setminus Z_i$, and (iii) S is closed for player 1 in \mathcal{G}_i .*

Proof. We show the two points separately.

1. By $S \subseteq V \setminus Z_i$ we have for all $v \in S \cap V_1$ that $\text{Out}(G, v) = \text{Out}(G_i, v)$. Thus if $\text{Out}(G_i, v) \subseteq S$, then also $\text{Out}(G, v) \subseteq S$. Each edge of G_i is contained in G , thus we have for all $v \in S \cap V_2$ that $\text{Out}(G_i, v) \cap S \neq \emptyset$ implies $\text{Out}(G, v) \cap S \neq \emptyset$.
2. Since S is closed for player 1 and $|S| \leq 2^i$, (a) the set S does not contain vertices $v \in V_1$ with $\text{Outdeg}(G, v) > 2^i$. Further for every vertex of S also the vertices in V_2 from

which it has incoming edges are contained in $\text{Attr}_2(\mathcal{G}, S)$. Thus by $|\text{Attr}_2(\mathcal{G}, S)| \leq 2^i$ no vertex of S has more than 2^i incoming edges from vertices of V_2 . Hence, by the ordering of incoming edges in the construction of G_i , we obtain (b) for the vertices of S all incoming edges from vertices of V_2 are contained in E_i . Combining (a), i.e., $\text{Out}(G, v) = \text{Out}(G_i, v)$ for $v \in S \cap V_1$, and (b), i.e., $(u, w) \in E_i$ for $u \in V_2$ and $w \in S$, we have (i) $\mathcal{G}_i[S] = \mathcal{G}[S]$. Since S is closed for player 1 in \mathcal{G} , every vertex $u \in S \cap V_2$ has an outgoing edge to another vertex $w \in S$ in \mathcal{G} . Thus in particular these edges (u, w) are contained in E_i and hence every vertex $u \in S \cap V_2$ has an outgoing edge to another vertex $w \in S$ in G_i . It follows that (ii) $S \cap Z_i = \emptyset$, and (iii) S is closed for player 1 in \mathcal{G}_i (by (1)). \square

That is, in all but the last iteration of Algorithm **GENBUCHIGAME** whenever the graph G_i is considered a dominion of size at least 2^{i-1} is identified and removed from the graph.

Corollary 3.5. *If in Algorithm **GENBUCHIGAME** for some ℓ, j , and $i > 1$ we have that $S^j = V^j \setminus \text{Attr}_1(\mathcal{G}_i^j, T_\ell^j \cup Z_i^j)$ is not empty but for $i - 1$ the set $V^j \setminus \text{Attr}_1(\mathcal{G}_{i-1}^j, T_\ell^j \cup Z_{i-1}^j)$ is empty, then $|\text{Attr}_2(\mathcal{G}^j, S^j)| > 2^{i-1}$.*

Proof. By Lemma 2.2(3) S^j is closed for player 1 in \mathcal{G}_i^j and by Lemma 3.4(1) also in \mathcal{G}^j . Assume by contradiction that $|\text{Attr}_2(\mathcal{G}^j, S^j)| \leq 2^{i-1}$. Then by Lemma 3.4(2) we have that $S^j \subseteq V^j \setminus Z_{i-1}^j$ and S^j is closed for player 1 in \mathcal{G}_{i-1}^j . Since this means that in \mathcal{G}_{i-1}^j player 1 has a strategy to keep a play within S^j against any strategy of player 2 and S^j does not contain a vertex of Z_{i-1}^j or T_ℓ^j , the set S^j does not intersect with $\text{Attr}_1(\mathcal{G}_{i-1}^j, T_\ell^j \cup Z_{i-1}^j)$, a contradiction to $V^j \setminus \text{Attr}_1(\mathcal{G}_{i-1}^j, T_\ell^j \cup Z_{i-1}^j)$ being empty. \square

We next two Propositions show the correctness of the algorithm by (i) showing that all vertices in the final set V^j are winning for player 1 and (ii) all vertices not in V^j are winning for player 2.

Proposition 3.6 (Soundness Algorithm **GENBUCHIGAME**). *Let V^{j*} be the set returned by the algorithm. Each vertex in V^{j*} is winning for player 1.*

Proof. When the algorithm terminates we have $i = \lceil \log_2 n \rceil$ and $S^j = \emptyset$. Since for $i = \lceil \log_2 n \rceil$ we have $G_i^j = G^j$ and $Z_i^j = \emptyset$, the winning strategy of player 1 can be constructed in the same way as for the set returned by Algorithm **GENBUCHIGAMEBASIC** (cf. Proof of Proposition 3.2). \square

Proposition 3.7 (Completeness Algorithm **GENBUCHIGAME**). *Let V^{j*} be the set returned by the algorithm. Player 2 has a winning strategy from each vertex in $V \setminus V^{j*}$.*

Proof. By Lemma 2.2(5) it is sufficient to show that, in each iteration j , player 2 has a winning strategy in \mathcal{G}^j from each vertex of S^j . For a fixed j with $S^j \neq \emptyset$, let i and ℓ be such that $S^j = V^j \setminus \text{Attr}_1(\mathcal{G}_i^j, T_\ell^j \cup Z_i^j)$. By Lemma 2.2(3) the set S^j is closed for player 1 in \mathcal{G}_i^j and by Lemma 3.4(1) also in \mathcal{G}^j . That is, player 2 has a strategy that keeps the play within $\mathcal{G}^j[S^j]$ against any strategy of player 1. Since $S^j \cap T_\ell^j = \emptyset$, this strategy is winning for player 2 (i.e., satisfies the disjunctive co-Büchi objective). \square

Finally, the $O(k \cdot n^2)$ runtime bound is by Corollary 3.5, Lemma 2.2(2) and the fact that we can construct the graphs G_i efficiently.

Proposition 3.8 (Runtime Algorithm **GENBUCHIGAME**). *The algorithm can be implemented to terminate in $O(k \cdot n^2)$ time.*

Proof. To efficiently construct the graphs G_i^j and the vertex sets Z_i^j we maintain (sorted) lists of the incoming and the outgoing edges of each vertex. These lists can be updated whenever an obsolete entry is encountered in the construction of G_i^j ; as each entry is removed at most once, maintaining this data structures takes total time $O(m)$. For a given iteration j of the outer repeat-until loop and the i th iteration of the inner repeat-until loop we have that the graph G_i^j contains $O(2^i \cdot n)$ edges and both G_i^j and the set Z_i^j can be constructed from the maintained lists in time $O(2^i \cdot n)$. Further the k attractor computations in the for-loop can be done in time $O(k \cdot 2^i \cdot n)$, thus for any j the i th iteration of the inner repeat-until loop takes time $O(k \cdot 2^i \cdot n)$. The time spent in the iterations up to the i th iteration forms a geometric series and can thus also be bounded by $O(k \cdot 2^i \cdot n)$. When a non-empty set S^j is found in the j th iteration of the outer repeat-until and in the i th iteration of the inner repeat-until loop, then by Corollary 3.5 we have $|Attr_2(\mathcal{G}^j, S^j)| > 2^{i-1}$. The vertices in $Attr_2(\mathcal{G}^j, S^j)$ are then removed from G^j to obtain G^{j+1} and are not considered further by the algorithm. Thus we can charge the time of $O(k \cdot 2^i \cdot n)$ to identify S^j to the vertices in $Attr_2(\mathcal{G}^j, S^j)$, which yields a bound on the total time spent in the inner repeat-until loop, whenever $S^j \neq \emptyset$, of $O(k \cdot n^2)$. By Lemma 2.2(2) the total time for computing the attractors $Attr_2(\mathcal{G}^j, S^j)$ can be bounded by $O(m)$. Finally the time for the last iteration of the while loop, when $S^j = \emptyset$ and $i = \lceil \log_2 n \rceil$, can be bounded by $O(k \cdot 2^{\lceil \log_2 n \rceil} \cdot n) = O(k \cdot n^2)$. \square

Remark 3.9. Algorithm **GENBUCHIGAME** can easily be modified to also return winning strategies for both players within the same time bound: For player 2 a winning strategy for the dominion D^j that is identified in iteration j of the algorithm can be constructed by combining his strategy to stay within the set S^j that is closed for player 1 with his attractor strategy to the set S^j . For player 1 we can obtain a winning strategy by combining her attractor strategies to the sets T_ℓ for $1 \leq \ell \leq k$ (as described in the proof of Proposition 3.2).

4 Conditional Lower bounds for Generalized Büchi Games

In this section we present two conditional lower bounds, one for dense graphs ($m = \Theta(n^2)$) based on STC & BMM, and one for sparse graphs ($m = \Theta(n^{1+o(1)})$) based on OVC & SETH.

Theorem 4.1. *There is no combinatorial $O(n^{3-\epsilon})$ or $O((k \cdot n^2)^{1-\epsilon})$ -time algorithm (for any $\epsilon > 0$) for generalized Büchi games under Conjecture 2.4 (i.e., unless STC & BMM fail). In particular, there is no such algorithm deciding whether the winning set is non-empty or deciding whether a specific vertex is in the winning set.*

The result can be obtained from a reduction from triangle detection to disjunctive co-Büchi objectives on graphs in [CDH⁺16], and we present the reduction in terms of game graphs below and illustrate it on an example in Figure 2.

Reduction 4.2. *Given a graph $G = (V, E)$ (for triangle detection), we build a game graph $\mathcal{G}' = ((V', E'), (V_1, V_2))$ (for generalized Büchi objectives) as follows. As vertices V' we have four copies V^1, V^2, V^3, V^4 of V and a vertex s . A vertex $v^i \in V^i, i \in \{1, 2, 3\}$ has an edge to a vertex $u^{i+1} \in V^{i+1}$ iff $(v, u) \in E$. Moreover, s has an edge to all vertices of V^1 and*

Figure 2: Illustration of Reduction 4.2, with $G = (\{a, b, c, d\}, \{(a, b), (b, a), (b, c), (c, a), (c, d), (d, a)\})$. The target sets for disjunctive co-Büchi are $T_a = \{b^1, c^1, d^1, b^4, c^4, d^4\}$, $T_b = \{a^1, c^1, d^1, a^4, c^4, d^4\}$, $T_c = \{a^1, b^1, d^1, a^4, b^4, d^4\}$, and $T_d = \{a^1, b^1, c^1, a^4, b^4, c^4\}$.

all vertices of V^4 have an edge to s . All the vertices are owned by player 2, i.e., $V_1 = \emptyset$ and $V_2 = V$. Finally, we consider the generalized Büchi objective $\bigwedge_{v \in V} \text{Büchi}(T_v)$, with $T_v = (V^1 \setminus \{v^1\}) \cup (V^4 \setminus \{v^4\})$.

The game graph \mathcal{G}' is constructed such that there is a triangle in the graph G if and only if the vertex s is winning for player 2 in the generalized Büchi game on \mathcal{G}' . For instance consider the example in Figure 2. The graph G has a triangle a, b, c and this triangle gives rise to the following winning strategy for player 2 starting at vertex s . When a play is in the vertex s then player 2 moves to vertex a^1 , when in a^1 he moves to b^2 , when in b^2 he moves to c^3 , when in c^3 he moves to a^4 , and finally from a^4 he moves back to s . This strategy does not visit any vertex of the set T_a and thus the conjunctive Büchi objective of player 1 is not satisfied, i.e., player 2 wins. The following Lemma we show that also the other direction holds, i.e., that a memoryless winning strategy from s gives rise to a triangle in the original graph. This correspondence between triangles and memoryless winning strategies then gives the correctness of the reduction.

Lemma 4.3. *Let \mathcal{G}' be the game graph given by Reduction 4.2 for a graph G and let $T_v = (V^1 \setminus \{v^1\}) \cup (V^4 \setminus \{v^4\})$. Then the following statements are equivalent.*

1. G has a triangle.
2. $s \notin W_1(\mathcal{G}', \bigwedge_{v \in V} \text{Büchi}(T_v))$.
3. The winning set $W_1(\mathcal{G}', \bigwedge_{v \in V} \text{Büchi}(T_v))$ is empty.

Proof. (1) \Rightarrow (2): Assume that G has a triangle with vertices a, b, c and let a^i, b^i, c^i be the copies of a, b, c in V^i . Now a strategy for player 2 in \mathcal{G}' to satisfy $\text{coBüchi}(T_a)$ is as follows: When in s , go to a^1 ; when in a^1 , go to b^2 ; when in b^2 , go to c^3 ; when in c^3 , go to a^4 ; and when in a^4 , go to s . As a, b, c form a triangle, all the edges required by the above strategy exist. When player 2 starts at s and follows the above strategy, then he plays an infinite path that only uses the vertices s, a^1, b^2, c^3, a^4 and thus satisfies $\text{coBüchi}(T_a)$.

(2) \Rightarrow (1): Assume that there is a memoryless winning strategy for player 2 starting in s and satisfying $\text{coBüchi}(T_a)$. Starting from s , this strategy has to go to a^1 , as all other

successors of s are contained in T_a and thus would violate the coBüchi(T_a) objective. Then the play continues on some vertex $b^2 \in V^2$ and $c^3 \in V^3$ and then, again by the coBüchi constraint, has to enter a^4 . Now by construction of \mathcal{G}' we know that there must be edges $(a, b), (b, c), (c, a)$ in the original graph G , i.e. there is a triangle in G .

(2) \Leftrightarrow (3): Notice that when removing s from \mathcal{G}' we get an acyclic graph and thus each infinite path has to contain s infinitely often. Thus, if the winning set is non-empty, there is a cycle winning for some vertex and then this cycle is also winning for s . For the converse direction we have that if s is in the winning set, then the winning set is non-empty. \square

The size and the construction time of the game graph \mathcal{G}' , given in Reduction 4.2, are linear in the size of the original graph G and we have $k = \Theta(n)$ target sets. Thus if we would have a combinatorial $O(n^{3-\epsilon})$ or $O((k \cdot n^2)^{1-\epsilon})$ algorithm for generalized Büchi games, we would immediately get a combinatorial $O(n^{3-\epsilon})$ algorithm for triangle detection, which contradicts STC (and thus BMM).

Notice that the sets T_v in the above reduction are of linear size but can be reduced to logarithmic size by modifying the graph constructed in Reduction 4.2 as follows. Remove all edges incident to s and replace them by two complete binary trees. The first tree with s as root and the vertices V^1 as leaves is directed towards the leaves, the second tree with root s and leaves V^4 is directed towards s . Now for each pair v^1, v^4 one can select one vertex of each non-root level of the trees to be in the set T_v such that the only winning path for player 2 starting in s has to use v^1 and each winning path for player 2 to s must pass v^4 (see also [CDH⁺16]).

Next we present an $\Omega(m^{2-o(1)})$ lower bound for generalized Büchi objectives in sparse game graphs based on OVC and SETH.

Theorem 4.4. *There is no $O(m^{2-\epsilon})$ or $O(\min_{1 \leq i \leq k} b_i \cdot (k \cdot m)^{1-\epsilon})$ -time algorithm (for any $\epsilon > 0$) for generalized Büchi games under Conjecture 2.6 (i.e., unless OVC and SETH fail). In particular, there is no such algorithm for deciding whether the winning set is non-empty or deciding whether a specific vertex is in the winning set.*

The above theorem is by a linear time reduction from OV provided below, and illustrated on an example in Figure 3.

Reduction 4.5. *Given two sets S_1, S_2 of d -dimensional vectors, we build the following game graph $\mathcal{G} = ((V, E), (V_1, V_2))$.*

- *The vertices V are given by a start vertex s , sets of vertices S_1 and S_2 representing the sets of vectors, and a set of vertices $\mathcal{C} = \{c_i \mid 1 \leq i \leq d\}$ representing the coordinates. The edges E are defined as follows: the start vertex s has an edge to every vertex of S_1 and every vertex of S_2 has an edge to s ; further for each $x \in S_1$ there is an edge to $c_i \in \mathcal{C}$ iff $x_i = 1$ and for each $y \in S_2$ there is an edge from $c_i \in \mathcal{C}$ iff $y_i = 1$.*
- *The set of vertices V is partitioned into player 1 vertices $V_1 = S_1 \cup S_2 \cup \mathcal{C}$ and player 2 vertices $V_2 = \{s\}$.*

Finally, the generalized Büchi objective is given by $\bigwedge_{v \in S_2} \text{Büchi}(T_v)$ with $T_v = \{v\}$.

The correctness of the reduction is by the following lemma.

Figure 3: Illustration of Reduction 4.5, for $S_1 = \{(1, 0, 0), (1, 1, 1), (0, 1, 1)\}$ and $S_2 = \{(1, 1, 0), (1, 1, 1), (0, 1, 0), (0, 0, 1)\}$.

Lemma 4.6. *Given two sets S_1, S_2 of d -dimensional vectors, the corresponding graph game \mathcal{G} given by Reduction 4.5, and $T_v = \{v\}$ for $v \in S_2$, the following statements are equivalent:*

1. *There exist orthogonal vectors $x \in S_1$ and $y \in S_2$.*
2. *$s \notin W_1(\mathcal{G}, \bigwedge_{v \in S_2} \text{Büchi}(T_v))$*
3. *The winning set $W_1(\mathcal{G}, \bigwedge_{v \in S_2} \text{Büchi}(T_v))$ is empty.*

Proof. W.l.o.g. we assume that the 1-vector, i.e., the vector with all coordinates being 1, is contained in S_2 (adding the 1-vector does not change the result of the OV instance), which guarantees that each vertex $c \in \mathcal{C}$ has at least 1 outgoing edge. Then a play in the game graph \mathcal{G} proceeds as follows. Starting from s , player 2 chooses a vertex $x \in S_1$; then player 1 first picks a vertex $c \in \mathcal{C}$ and then a vertex $y \in S_2$; then the play goes back to s (at each $y \in S_2$ player 1 has only this choice), starting another cycle of the play.

(1) \Rightarrow (2): Assume there are orthogonal vectors $x \in S_1$ and $y \in S_2$. Now player 2 can satisfy $\text{coBüchi}(T_y)$ by simply going to x whenever the play is in s . Then player 1 can choose some adjacent $c \in \mathcal{C}$ and then some adjacent vertex in S_2 , but as x and y are orthogonal, this c is not connected to y . Thus the play will never visit y .

(2) \Rightarrow (1): By the fact that generalized Büchi games satisfy Determinacy, i.e., $W_1 = V \setminus W_2$ (cf. Theorem 2.1), we have that (2) is equivalent to $s \in W_2(\mathcal{G}, \bigwedge_{v \in S_2} \text{Büchi}(T_v))$. Assume $s \in W_2(\mathcal{G}, \bigwedge_{v \in S_2} \text{Büchi}(T_v))$ and consider a corresponding strategy for player 2 that satisfies $\bigvee_{v \in S_2} \text{coBüchi}(T_v)$. Notice that the graph is such that player 2 has to visit at least one of the vertices v in S_1 infinitely often. Moreover, for such a vertex v then player 1 can visit all vertices $v' \in S_2$ that correspond to vectors not orthogonal to v infinitely often. That is, if v has no orthogonal vector, player 1 can satisfy all the Büchi constraints, a contradiction to our assumption that $s \in W_2(\mathcal{G}, \bigwedge_{v \in S_2} \text{Büchi}(T_v))$. Thus there must be a vector $x \in S_1$ such that there exists a vector $y \in S_2$ that is orthogonal to x .

(2) \Leftrightarrow (3): Notice that when removing s from the graph we get an acyclic graph and thus each infinite path has to contain s infinitely often. Certainly if s is in the winning set

of player 1, this set is non-empty. Thus let us assume there is a vertex v different from s with a winning strategy σ . All (winning) paths starting in v cross s after at most 3 steps and thus the strategy σ is also winning for player 1 when the play starts at s . \square

Let $N = \max(|S_1|, |S_2|)$. The number of vertices in the game graph, constructed by Reduction 4.5, is $O(N)$, the number of edges m is $O(N \log N)$ (recall that $d \in O(\log N)$), we have $k \in \Theta(N)$ target sets, each of size 1, and the construction can be performed in $O(N \log N)$ time. Thus, if we would have an $O(m^{2-\epsilon})$ or $O(\min_{1 \leq i \leq k} b_i \cdot (k \cdot m)^{1-\epsilon})$ time algorithm for any $\epsilon > 0$, we would immediately get an $O(N^{2-\epsilon})$ algorithm for OV, which contradicts OVC (and thus SETH).

Remark 4.7. Notice that the conditional lower bounds apply to instances with $k \in \Theta(n^c)$ for arbitrary $0 < c \leq 1$, although the reductions produce graphs with $k \in \Theta(n)$. The instances constructed by the reductions have the property that whenever player 2 has a winning strategy, he also has a winning strategy for a specific co-Büchi set T_v . Now instead of solving the instance with $\Theta(n)$ many target sets, one can simply consider $O(n^{1-c})$ many instances with $\Theta(n^c)$ target sets and obtain the winning set for player 2 in the original instance by the union of the player 2 winning sets of the new instances. Finally, towards a contradiction, assume there would be an $O((k \cdot f(n, m))^{1-\epsilon})$ -time algorithm for $k \in \Theta(n^c)$. Then together with the above observation we would get an $O((k \cdot f(n, m))^{1-\epsilon})$ -time algorithm for the original instance.

Remark 4.8. In both reductions the constructed graph becomes acyclic when deleting vertex s . Thus, our lower bounds also apply for a broad range of digraph parameters. For instance let w be the DAG-width [BDH⁺06] of a graph, then there is no $O(f(w) \cdot (k \cdot n^2)^{1-\epsilon})$ -time algorithm (under BMM) and no $O(f(w) \cdot (km)^{1-\epsilon})$ -time algorithm (under SETH).

5 Generalized Reactivity-1 Games

GR(1) games deal with an objective of the form $\bigwedge_{t=1}^{k_1} \text{Büchi}(L_t) \rightarrow \bigwedge_{\ell=1}^{k_2} \text{Büchi}(U_\ell)$ and can be solved in $O(k_1 k_2 \cdot m \cdot n)$ time [JP06] with an extension of the progress measure algorithm of [Jur00] and in $O((k_1 k_2 \cdot n)^{2.5})$ time by combining the reduction to one-pair Streett objectives by [BCG⁺10] with the algorithm of [CHL15]. In this section we develop an $O(k_1 k_2 \cdot n^{2.5})$ -time algorithm by modifying the algorithm of [JP06] to compute dominions. We further use our $O(k \cdot n^2)$ -time algorithm for generalized Büchi games with $k = k_1$ as a subroutine.

Section Outline. We first describe a basic, direct algorithm for GR(1) games that is based on repeatedly identifying player-2 dominions in generalized Büchi games. We then show how the progress measure algorithm of [JP06] can be modified to identify player-2 dominions in generalized Büchi games with k_1 Büchi objectives in time proportional to $k_1 \cdot m$ times the size of the dominion. In the $O(k_1 k_2 \cdot n^{2.5})$ -time algorithm we use the modified progress measure algorithm in combination with the hierarchical graph decomposition of [CH14, CHL15] to identify dominions that contain up to \sqrt{n} vertices and our $O(k_1 \cdot n^2)$ -time algorithm for generalized Büchi games to identify dominions with more than \sqrt{n} vertices. Each time we search for a dominion we might have to consider k_2 different subgraphs.

Notation. In the algorithms and their analysis we denote the sets in the j th-iteration of our algorithms with superscript j , in particular $\mathcal{G}^1 = \mathcal{G}$, where \mathcal{G} is the input game graph, G^j is

the graph of \mathcal{G}^j , V^j is the vertex set of G^j , $V_1^j = V_1 \cap V^j$, $V_2^j = V_2 \cap V^j$, $L_t^j = L_t \cap V^j$, and $U_\ell^j = U_\ell \cap V^j$.

5.1 Basic Algorithm for GR(1) Objectives

Similar to generalized Büchi games, the basic algorithm for GR(1) games, described in Algorithm **GR(1)GAMEBASIC**, identifies a player-2 dominion S^j , removes the dominion and its player-2 attractor D^j from the graph, and recurses on the remaining game graph $\mathcal{G}^{j+1} = \mathcal{G}^j \setminus D^j$. If no player-2 dominion is found, the remaining set of vertices V^j is returned as the winning set of player 1. Given the set S^j is indeed a player-2 dominion, the correctness of this approach follows from Lemma 2.2(5). A player-2 dominion in \mathcal{G}^j is identified as follows: For each $1 \leq \ell \leq k_2$ first the player-1 attractor Y_ℓ^j of U_ℓ^j is temporarily removed from the graph. Then a generalized Büchi game with target sets $L_1^j, \dots, L_{k_1}^j$ is solved on $\overline{\mathcal{G}^j \setminus Y_\ell^j}$. The generalized Büchi player in this game corresponds to player 2 in the GR(1) game and his winning set to a player-2 dominion in the GR(1) game. Note that $V^j \setminus Y_\ell^j$ is player-1 closed and does not contain U_ℓ^j . Thus if in the game induced by the vertices of $V^j \setminus Y_\ell^j$ player 2 can win w.r.t. the generalized Büchi objective $\bigwedge_{t=1}^{k_1} \text{Büchi}(L_t^j)$, then these vertices form a player-2 dominion in the GR(1) game. This observation is formalized in Lemma 5.2. Further, we can show that when a player-2 dominion in the GR(1) game on \mathcal{G}^j exists, then for one of the sets U_ℓ^j the winning set of the generalized Büchi game on $\overline{\mathcal{G}^j \setminus Y_\ell^j}$ is non-empty; otherwise we can construct a winning strategy of player 1 for the GR(1) game on \mathcal{G}^j (see Lemma 5.3 and Proposition 5.4). Note that this algorithm computes a player-2 dominion $O(k_2 \cdot n)$ often using our $O(k_1 \cdot n^2)$ -time generalized Büchi Algorithm **GENBÜCHIGAME** from Section 3.2.

Theorem 5.1. *The basic algorithm for GR(1) games computes the winning set of player 1 in $O(k_1 \cdot k_2 \cdot n^3)$ time.*

We first show that the dominions we compute via the generalized Büchi games are indeed player-2 dominions for the GR(1) game.

Lemma 5.2. *We are given a game with game graph \mathcal{G} and GR(1) objective $\bigwedge_{t=1}^{k_1} \text{Büchi}(L_t) \rightarrow \bigwedge_{\ell=1}^{k_2} \text{Büchi}(U_\ell)$. Each player-1 dominion D of the game graph $\overline{\mathcal{G}}$ with generalized Büchi objective $\bigwedge_{t=1}^{k_1} \text{Büchi}(L_t)$, for which there is an index $1 \leq \ell \leq k_2$ with $D \cap U_\ell = \emptyset$, is a player-2 dominion of \mathcal{G} with the original GR(1) objective.*

Proof. By definition of a dominion, in $\overline{\mathcal{G}}$ player 1 has a strategy that visits all sets L_t infinitely often and only visits vertices in D . But then for some ℓ the Büchi set U_ℓ is not visited at all and thus in \mathcal{G} the strategy is winning for player 2 w.r.t. the GR(1) objective. \square

Next we show that each player-2 dominion contains a sub-dominion that does not intersect with one of the sets U_ℓ , and thus can be computed via generalized Büchi games.

Lemma 5.3. *We are given a game with game graph \mathcal{G} and GR(1) objective $\bigwedge_{t=1}^{k_1} \text{Büchi}(L_t) \rightarrow \bigwedge_{\ell=1}^{k_2} \text{Büchi}(U_\ell)$. Each player-2 dominion D has a subset $D' \subseteq D$ that is a player-2 dominion with $D' \cap U_\ell = \emptyset$ for some $1 \leq \ell \leq k_2$.*

Proof. First, note that D is closed for player-1 and thus by the definition of a 2-dominion we have that D is equal to $W_2(\mathcal{G}[D], \bigwedge_{t=1}^{k_1} \text{Büchi}(L_t \cap D) \rightarrow \bigwedge_{\ell=1}^{k_2} \text{Büchi}(U_\ell \cap D))$. Moreover,

Algorithm GR(1)GAMEBASIC: GR(1) Games in $O(k_1 \cdot k_2 \cdot n^3)$ Time

Input : Game graph \mathcal{G} , Obj. $\bigwedge_{t=1}^{k_1} \text{Büchi}(L_t) \rightarrow \bigwedge_{\ell=1}^{k_2} \text{Büchi}(U_\ell)$
Output: Winning set of player 1

```

1  $\mathcal{G}^1 \leftarrow \mathcal{G}$ 
2  $\{U_\ell^1\} \leftarrow \{U_\ell\}; \{L_t^1\} \leftarrow \{L_t\}$ 
3  $j \leftarrow 0$ 
4 repeat
5    $j \leftarrow j + 1$ 
6   for  $1 \leq \ell \leq k_2$  do
7      $Y_\ell^j \leftarrow \text{Attr}_1(\mathcal{G}^j, U_\ell^j)$ 
8      $S^j \leftarrow W_1(\mathcal{G}^j \setminus Y_\ell^j, \bigwedge_{t=1}^{k_1} \text{Büchi}(L_t^j \setminus Y_\ell^j))$ 
9     if  $S^j \neq \emptyset$  then break
10   $D^j \leftarrow \text{Attr}_2(\mathcal{G}^j, S^j)$ 
11   $\mathcal{G}^{j+1} \leftarrow \mathcal{G}^j \setminus D^j$ 
12   $\{U_\ell^{j+1}\} \leftarrow \{U_\ell^j \setminus D^j\}; \{L_t^{j+1}\} \leftarrow \{L_t^j \setminus D^j\}$ 
13 until  $D^j = \emptyset$ 
14 return  $V^j$ 

```

as each 1-closed set in $\mathcal{G}[D]$ is also 1-closed in \mathcal{G} , a set $D' \subseteq D$ is a player-2 dominion of \mathcal{G} iff it is a player-2 dominion of $\mathcal{G}[D]$.

Towards a contradiction, assume that there does not exist such a player-2 dominion D' in $\mathcal{G}[D]$. We will show that then player 1 can win from the vertices of D . By the assumption we have that player-1 has a winning strategy for each $1 \leq \ell \leq k_2$ for the game graph $\mathcal{G}^\ell[D] = \mathcal{G}[D] \setminus \text{Attr}_1(\mathcal{G}[D], U_\ell)$ w.r.t. the GR(1) objective. As $U_\ell \cap \mathcal{G}^\ell[D] = \emptyset$, the same strategy is also winning for the disjunctive co-Büchi objective $\bigvee_{t=1}^{k_1} \text{coBüchi}(L_t)$. Now consider the following strategy for player 1 in $\mathcal{G}[D]$. The winning strategy of player 1 is constructed from her winning strategies for the game graphs $\mathcal{G}^\ell[D]$ and the attractor strategies for $\text{Attr}_1(\mathcal{G}[D], U_\ell)$ for $1 \leq \ell \leq k_2$ as follows. Player 1 maintains a counter $c \in \{1, \dots, k_2\}$ that is initialized to 1. As long as the current vertex in the play is contained in $\mathcal{G}^c[D]$, player 1 plays her winning strategy for $\mathcal{G}^c[D]$. If a vertex of $\text{Attr}_1(\mathcal{G}[D], U_c)$ is reached, player 1 follows the corresponding attractor strategy until U_c is reached. Then player 1 increases the counter by one or sets the counter to 1 if its value was k_2 and continues playing the above strategy for the new value c . In each play one of two cases must happen:

- Case 1: After some prefix of the play for some counter value c the set $\text{Attr}_1(\mathcal{G}[D], U_c)$ is never reached. Then the play satisfies the disjunctive co-Büchi objective $\bigvee_{t=1}^{k_1} \text{coBüchi}(L_t)$ and thus the GR(1) objective.
- Case 2: For all $c \in \{1, \dots, k_2\}$ the set U_c is reached infinitely often. Then the play satisfies the generalized Büchi objective $\bigwedge_{\ell=1}^{k_2} \text{Büchi}(U_\ell)$ and thus the GR(1) objective.

Hence, we have shown that $D \subseteq W_1$, a contradiction. \square

Let the j^* -th iteration be the last iteration of Algorithm GR(1)GAMEBASIC. For the

final game graph \mathcal{G}^{j*} we can build a winning strategy for player 1 by combining her winning strategies for the disjunctive objective in the subgraphs \mathcal{G}_ℓ^{j*} and the attractor strategies for $\text{Attr}_1(\mathcal{G}^{j*}, U_\ell)$.

Proposition 5.4 (Soundness Algorithm **GR(1)GAMEBASIC**). *Let V^{j*} be the set of vertices returned by Algorithm **GR(1)GAMEBASIC**. Each vertex in V^{j*} is winning for player 1.*

Proof. First note that V^{j*} is closed for player 2 by Lemma 2.2(3). Thus as long as player 1 plays a strategy that stays within V^{j*} , a play that reaches V^{j*} will never leave V^{j*} . The following strategy for player 1 for the vertices of V^{j*} satisfies this condition. The winning strategy of player 1 is constructed from the winning strategies of the disjunctive co-Büchi player, i.e., player 2, in the generalized Büchi games with game graphs $\overline{\mathcal{G}_\ell^{j*}} = \overline{\mathcal{G}^{j*} \setminus Y_\ell^{j*}}$ and objectives $\bigwedge_{t=1}^{k_1} \text{Büchi}(L_t^{j*} \setminus Y_\ell^{j*})$ and the attractor strategies for $\text{Attr}_1(\mathcal{G}^{j*}, U_\ell^{j*})$ for $1 \leq \ell \leq k_2$. Player 1 maintains a counter $c \in \{1, \dots, k_2\}$ that is initialized to 1 and proceeds as follows. (1) As long as the current vertex in the play is contained in $G_c^{j*} = \mathcal{G}^{j*} \setminus Y_c^{j*}$, player 1 plays her winning strategy for the disjunctive co-Büchi objective on \mathcal{G}_c^{j*} . (2) If a vertex of $Y_c^{j*} = \text{Attr}_1(\mathcal{G}^{j*}, U_c^{j*})$ is reached, player 1 follows the corresponding attractor strategy until U_c^{j*} is reached. Then player 1 increases the counter by one, or sets the counter to 1 if its value was k_2 , and continues with (1). As the play stays within V_1^{j*} , one of two cases must happen: Case 1: After some prefix of the play for some counter value c the set $\text{Attr}_1(\mathcal{G}^{j*}, U_c^{j*})$ is never reached. Then the play satisfies the disjunctive co-Büchi objective $\bigvee_{t=1}^{k_1} \text{coBüchi}(L_t)$ and thus the GR(1) objective. Case 2: For all $c \in \{1, \dots, k_2\}$ the set U_c^{j*} is reached infinitely often. Then the play satisfies the generalized Büchi objective $\bigwedge_{\ell=1}^{k_2} \text{Büchi}(U_\ell)$ and thus the GR(1) objective. \square

We show next that whenever Algorithm **GR(1)GAMEBASIC** removes vertices from the game graph, these vertices are indeed winning for player 2. This is due to Lemma 5.2 that states that these sets are dominions in the current game graph, and Lemma 2.2(5) that states that all player-2 dominions of the current game graph \mathcal{G}^j are also winning for player 2 in the original game graph \mathcal{G} .

Proposition 5.5 (Completeness Algorithm **GR(1)GAMEBASIC**). *Let V^{j*} be the set of vertices returned by Algorithm **GR(1)GAMEBASIC**. Each vertex in $V \setminus V^{j*}$ is winning for player 2.*

Proof. By Lemma 2.2(5) it is sufficient to show that in each iteration j with $S^j \neq \emptyset$ player 2 has a winning strategy from the vertices in S^j in \mathcal{G}^j . Let j be such that $S^j = W_1(\overline{\mathcal{G}^j \setminus Y_\ell^j}, \bigwedge_{t=1}^{k_1} \text{Büchi}(L_t^j \setminus Y_\ell^j))$. We first show that S^j is also a player-1 dominion for the generalized Büchi game on the game graph $\overline{\mathcal{G}^j}$ that includes the vertices of Y_ℓ^j , i.e., that S is a player-2 dominion on \mathcal{G}^j . By Lemma 2.2(3) the set $V^j \setminus Y_\ell^j$ is 1-closed in \mathcal{G}^j , i.e., it is 2-closed in $\overline{\mathcal{G}^j}$. Thus each 1-dominion of $\overline{\mathcal{G}^j \setminus Y_\ell^j}$ is also 2-closed in $\overline{\mathcal{G}^j}$ and hence a 1-dominion in $\overline{\mathcal{G}^j}$ (see also Lemma 2.2(4)). Now as S^j does not contain any vertices of U_ℓ , it is by Lemma 5.2 a player-2 dominion in \mathcal{G} w.r.t. the GR(1) objective. Finally, from the above and Lemma 2.2(1) we have that also $\text{Attr}_2(\mathcal{G}^j, S^j)$ is a player-2 dominion in \mathcal{G} with the GR(1) objective. \square

Finally the runtime of Algorithm **GR(1)GAMEBASIC** is the product of the number of iterations of the nested loops and the runtime for the generalized Büchi algorithm.

Proposition 5.6 (Runtime Algorithm **GR(1)GAMEBASIC**). *Algorithm **GR(1)GAMEBASIC** runs in $O(k_2 \cdot n \cdot B)$ where B is the runtime bound for the used ConjBüchi algorithm, i.e., if we use Algorithm **GENBÜCHIGAME** to solve ConjBüchi, the bound is $O(k_1 \cdot k_2 \cdot n^3)$.*

Proof. As in each iteration of the outer loop, except the last one, at least one vertex is removed from the maintained graph, there are only $O(n)$ iterations. In the inner loop we have k_2 iterations, each with a call to the generalized Büchi game algorithm. Thus, in total we have a running time of $O(k_2 \cdot n \cdot B)$. \square

5.2 Progress Measure Algorithm for Finding Small Dominions

Our goal for the remaining part Section 5 is to speed up the basic algorithm by computing “small” player-2 dominions faster such that in each iteration of the algorithm a “large” 2-dominion is found and thereby the number of iterations of the algorithm is reduced. To compute small dominions we use a *progress measure* for generalized Büchi games which is a special instance of the more general progress measure for GR(1) games presented in [JP06, Section 3.1], which itself is based on [Jur00]. In this section we first restate the progress measure of [JP06] in our notation and simplified to generalized Büchi, then adapt it to not compute the winning sets but dominions of a given size, and finally give an efficient algorithm to compute the progress measure.

The progress measure of [JP06] is defined as follows. Let $\bigwedge_{i=1}^k \text{Büchi}(T_i)$ be a generalized Büchi objective. For each $1 \leq \ell \leq k$ we define the value \bar{n}_ℓ to be $\bar{n}_\ell = |V \setminus T_\ell|$ and a function $\rho_\ell : V \rightarrow \{0, 1, \dots, \bar{n}_\ell, \infty\}$. The intuitive meaning of a value $\rho_\ell(v)$ is the number of moves player 1 needs, when starting in v , to reach a vertex of $T_\ell \cap W_1$, i.e., $\rho_\ell(v)$ will equal to the rank $\text{rank}_p(\mathcal{G}, T_\ell \cap W_1, v)$. As there are only \bar{n}_ℓ many vertices which are not in T_ℓ , one can either reach them within \bar{n}_ℓ steps or cannot reach them at all.

The actual value $\rho_\ell(v)$ is defined in a recursive fashion via the values of the successor vertices of v . That is, for $v \notin T_\ell$ we define $\rho_\ell(v)$ by the values $\rho_\ell(w)$ for $(v, w) \in E$. Otherwise, if $v \in T_\ell$, then we already reached T_ℓ and we only have to check whether v is in the winning set. That is, whether v can reach a vertex of the next target set $T_{\ell \oplus 1}$ that is also in the winning set W_1 . Hence, for $v \in T_\ell$ we define $\rho_\ell(v)$ by the values $\rho_{\ell \oplus 1}(w)$ for $(v, w) \in E$, where $\ell \oplus 1 = \ell + 1$ if $\ell < k$ and $k \oplus 1 = 1$ and analogously $\ell \ominus 1 = \ell - 1$ if $\ell > 1$ and $1 \ominus 1 = k$. For $v \in V$ one considers all the successor vertices and their values and then picks the minimum if $v \in V_1$ or the maximum if $v \in V_2$. In both cases $\rho_\ell(v)$ is set to this value increased by 1 if $v \notin T_\ell$. If $v \in T_\ell$, the value is set to ∞ if the minimum (resp. maximum) over the successors is ∞ and to 0 otherwise. This procedure is formalized via two functions. First, $\text{best}_\ell(v)$ returns the value of the best neighbor for the player owning v .

$$\text{best}_\ell(v) = \begin{cases} \min_{(v,w) \in E} \rho_{\ell \oplus 1}(w) & \text{if } v \in V_1 \wedge v \in T_\ell, \\ \min_{(v,w) \in E} \rho_\ell(w) & \text{if } v \in V_1 \wedge v \notin T_\ell, \\ \max_{(v,w) \in E} \rho_{\ell \oplus 1}(w) & \text{if } v \in V_2 \wedge v \in T_\ell, \\ \max_{(v,w) \in E} \rho_\ell(w) & \text{if } v \in V_2 \wedge v \notin T_\ell. \end{cases}$$

Second, the function $incr_v^\ell$ formalizes the incremental step described above. To this end, we define for each set $\{0, 1, \dots, \bar{n}_\ell, \infty\}$ the unary $++$ operator as $x++ = x + 1$ for $x < \bar{n}_\ell$ and $x++ = \infty$ otherwise.

$$incr_v^\ell(x) = \begin{cases} 0 & \text{if } v \in T_\ell \wedge x \neq \infty, \\ x++ & \text{otherwise.} \end{cases}$$

The functions $\rho_\ell(\cdot)$ are now defined as the least fixed-point of the operation that updates all $\rho_\ell(v)$ to $\max(\rho_\ell(v), incr_v^\ell(best_\ell(v)))$. The least fixed-point can be computed via the lifting algorithm [Jur00], that starts with all the $\rho_\ell(\cdot)$ initialized as the zero functions and iteratively updates $\rho_\ell(v)$ to $incr_v^\ell(best_\ell(v))$, for all $v \in V$, until the least fixed-point is reached.

Given the progress measure, we can decide the generalized Büchi game by the following theorem. Intuitively, player 1 can win starting from a vertex with $\rho_1(v) < \infty$ by keeping a counter ℓ that is initialized to 1, choosing the outgoing edge to $best_\ell(v)$ whenever at a vertex of V_1 , and increasing the counter with $\oplus 1$ when a vertex of T_ℓ is reached.

Theorem 5.7. [JP06, Thm. 1] *Player 1 has a winning strategy from a vertex v iff $\rho_1(v) < \infty$.*

As our goal is to compute small dominions, say of size h , instead of the whole winning set, we have to modify the above progress measure as follows. In the definition of the functions ρ_ℓ we redefine the value \bar{n}_ℓ to be $\min\{h - 1, |V \setminus T_\ell|\}$ instead of $|V \setminus T_\ell|$. The intuition behind this is that if the dominion contains at most h vertices, then from each vertex in the dominion we can reach each set T_ℓ within $h - 1$ steps and we do not care about vertices with a larger distance.

With Algorithm **GENBUCHI PROGRESS MEASURE** we give an $O(k \cdot h \cdot m)$ -time realization of the lifting algorithm for computing the functions ρ_ℓ . It is a corrected version of the lifting algorithm in [JP06, Section 3.1], tailored to generalized Büchi objectives and dominion computation, and exploits ideas from the lifting algorithm in [EWS05]. We iteratively increase the values $\rho_\ell(v)$ for all pairs (v, ℓ) . The main idea for the runtime bound is to consider each pair (v, ℓ) at most h times and each time we consider a pair we increase the value of $\rho_\ell(v)$ and only do computations in the order of the degree of v . To this end, we maintain a list of pairs (v, ℓ) for which $\rho_\ell(v)$ must be increased because of some update on v 's neighbors. We additionally maintain $B_\ell(v)$, which stores the value of $best_\ell(v)$ from the last time we updated $\rho_\ell(v)$, and a counter $C_\ell(v)$ for $v \in V_1$, which stores the number of successors $w \in Out(v)$ with $\rho_\ell(w) = B_\ell(v)$. Moreover, in order to initialize $C_\ell(v)$ when $B_\ell(v)$ is updated, we use the function $cnt_\ell(v)$ counting the number of successor vertices that have minimal ρ_ℓ . Notice that for $v \in T_\ell$ we only distinguish whether $\rho_{\ell \oplus 1}(v)$ is finite or not.

$$cnt_\ell(v) = \begin{cases} |\{w \in Out(v) \mid \rho_{\ell \oplus 1}(w) < \infty\}| & \text{if } v \in T_\ell, \\ |\{w \in Out(v) \mid \rho_\ell(w) = B_\ell(v)\}| & \text{if } v \notin T_\ell. \end{cases}$$

Whenever the algorithm considers a pair (v, ℓ) , it first computes $best_\ell(v)$, $cnt_\ell(v)$ in $O(Outdeg(v))$ time, stores these values in $B_\ell(v)$ and $C_\ell(v)$, and updates $\rho_\ell(v)$ to $incr_v^\ell(best_\ell(v))$. It then identifies the pairs (w, ℓ) , $(w, \ell \ominus 1)$ that are affected by the change of the value $\rho_\ell(v)$ and adds them to the set L in $O(Indeg(v))$ time.

In the remainder of the section we prove the following theorem.

Algorithm GENBUCHIPROGRESSMEASURE: Lifting Algorithm for Generalized Büchi Games

Input : Game graph $\mathcal{G} = ((V, E), (V_1, V_2))$, objective $\bigwedge_{1 \leq \ell \leq k} \text{Büchi}(T_\ell)$, integer $h \in [1, n]$

Output: player 1 dominion / winning set for player 1 if $h = n$

```

1 foreach  $v \in V, 1 \leq \ell \leq k$  do
2    $B_\ell(v) \leftarrow 0$ 
3   if  $v \in V_1$  then  $C_\ell(v) \leftarrow \text{Outdeg}(v)$ 
4    $\rho_\ell(v) \leftarrow 0$ 
5  $L \leftarrow \{(v, \ell) \mid v \in V, 1 \leq \ell \leq k, v \notin T_\ell\}$ 
6 while  $L \neq \emptyset$  do
7   pick some  $(v, \ell) \in L$  and remove it from  $L$ 
8    $\text{old} \leftarrow \rho_\ell(v)$ 
9    $B_\ell(v) \leftarrow \text{best}_\ell(v)$ 
10  if  $v \in V_1$  then  $C_\ell(v) \leftarrow \text{cnt}_\ell(v)$ 
11   $\rho_\ell(v) \leftarrow \text{incr}_v^\ell(\text{best}_\ell(v))$ 
12  foreach  $w \in \text{In}(v) \setminus T_\ell$  with  $(w, \ell) \notin L, \rho_\ell(w) < \infty$  do
13    if  $w \in V_1, \text{old} = B_\ell(w)$  then
14       $C_\ell(w) \leftarrow C_\ell(w) - 1$ 
15      if  $C_\ell(w) = 0$  then  $L \leftarrow L \cup \{(w, \ell)\}$ 
16    else if  $w \in V_2, \rho_\ell(v) > B_\ell(w)$  then  $L \leftarrow L \cup \{(w, \ell)\}$ 
17  if  $\rho_\ell(v) = \infty$  then
18    foreach  $w \in \text{In}(v) \cap T_{\ell \ominus 1}$  with  $(w, \ell \ominus 1) \notin L, \rho_{\ell \ominus 1}(w) < \infty$  do
19      if  $w \in V_1$  then
20         $C_{\ell \ominus 1}(w) \leftarrow C_{\ell \ominus 1}(w) - 1$ 
21        if  $C_{\ell \ominus 1}(w) = 0$  then  $L \leftarrow L \cup \{(w, \ell \ominus 1)\}$ 
22      else if  $w \in V_2$  then  $L \leftarrow L \cup \{(w, \ell \ominus 1)\}$ 
23 return  $\{v \in V \mid \rho_\ell(v) < \infty \text{ for some } \ell\}$ 

```

Theorem 5.8. For a game graph \mathcal{G} and objective $\psi = \bigwedge_{1 \leq \ell \leq k} \text{Büchi}(T_\ell)$, Algorithm **GENBUCHIPROGRESSMEASURE** is an $O(k \cdot h \cdot m)$ time procedure that either returns a player-1 dominion or the empty set, and, if there is at least one player-1 dominion of size $\leq h$ then returns a player-1 dominion containing all player-1 dominions of size $\leq h$.

Remark 5.9. While for the progress measure in [JP06] $\rho_\ell(v) < \infty$ for some $1 \leq \ell \leq k$ is equivalent to $\rho_{\ell'}(v) < \infty$ for all $1 \leq \ell' \leq k$, this does not hold in general for our modified progress measure ρ . Thus we consider the set $\{v \in V \mid \rho_\ell(v) < \infty \text{ for some } \ell\}$ as a player-1 dominion and not just the set $\{v \in V \mid \rho_1(v) < \infty\}$.

The correctness of Algorithm **GENBUCHIPROGRESSMEASURE** is by the following invariants that are maintained during the whole algorithm. These invariants show that (a) the data structures L , B_ℓ , and C_ℓ are maintained correctly, and (b) the values $\rho_\ell(v)$ are

bounded from above by (i) $\text{incr}_v^\ell(\text{best}_\ell(v))$ and (ii) by the rank $\text{rank}_1(\mathcal{G}, T_\ell \cap D, v)$ if v is in a dominion D of size $\leq h$.

Invariant 5.10. *The while loop in Algorithm GENBUCHIProgressMeasure has the following loop invariants.*

- (1) For all $v \in V$ and all $1 \leq \ell \leq k$ we have $\rho_\ell(v) \leq \text{incr}_v^\ell(\text{best}_\ell(v))$.
- (2) For all $v \in V$ and all $1 \leq \ell \leq k$ we have that if $\rho_\ell(v) \neq 0$ or $v \in T_\ell$, then $\rho_\ell(v) = \text{incr}_v^\ell(B_\ell(v))$.
- (3) For $v \in V_1$ we have $C_\ell(v) = \begin{cases} |\{w \in \text{Out}(v) \mid \rho_{\ell \oplus 1}(w) < \infty\}| & \text{if } v \in T_\ell, \\ |\{w \in \text{Out}(v) \mid \rho_\ell(w) = B_\ell(v)\}| & \text{if } v \notin T_\ell, \rho_\ell(v) < \infty. \end{cases}$
- (4) The set L consists exactly of the pairs (v, ℓ) with $\rho_\ell(v) < \text{incr}_v^\ell(\text{best}_\ell(v))$.
- (5) For each player-1 dominion D with $|D| \leq h$, for each $v \in D$ and all $1 \leq \ell \leq k$ we have $\rho_\ell(v) \leq \text{rank}_1(\mathcal{G}, T_\ell \cap D, v) < h$.

Notice that when the algorithm terminates we have by the Invariants (1) & (4) that $\rho_\ell(v) = \text{incr}_v^\ell(\text{best}_\ell(v))$ for all $v \in V$ and all $1 \leq \ell \leq k$, i.e., the functions $\rho_\ell(v)$ are a fixed-point for the $\text{incr}_v^\ell(\text{best}_\ell(v))$ updates. By the following lemmata we prove that the above loop invariants are valid.

Lemma 5.11. *After each iteration of the while loop in Algorithm GENBUCHIProgressMeasure we have $\rho_\ell(v) \leq \text{incr}_v^\ell(\text{best}_\ell(v))$, for all $v \in V$ and all $1 \leq \ell \leq k$.*

Proof. As all $\rho_\ell(v)$ are initialized to 0 and 0 is the minimum value, the inequalities are all satisfied in the *base case* when the algorithm first enters the while loop. Now for the *induction step* consider an iteration of the loop and assume the invariant is satisfied before the loop. The value $\rho_\ell(v)$ is only changed when the pair (v, ℓ) is processed and then it is set to $\text{incr}_v^\ell(\text{best}_\ell(v))$. Thus the invariant is satisfied after these iterations. In all the other iterations with different pairs (v', ℓ') the values $\rho_{\ell'}(v')$ are either unchanged or increased. As $\text{incr}_v^\ell(\text{best}_\ell(v))$ is monotonic in the values of the neighbors, this can only increase the right side of the inequality and thus this invariant is also satisfied after these iterations. Hence, if the invariant is valid before an iteration of the loop, it is also valid afterwards. \square

Lemma 5.12. *After each iteration of the while loop in Algorithm GENBUCHIProgressMeasure we have that if $\rho_\ell(v) \neq 0$ or $v \in T_\ell$, then $\rho_\ell(v) = \text{incr}_v^\ell(B_\ell(v))$, for all $v \in V$ and all $1 \leq \ell \leq k$.*

Proof. As $\rho_\ell(v)$ is initialized to 0, this is trivially satisfied in the *base case*. Now for the *induction step* consider an iteration of the loop and let us assume the invariant is satisfied before the loop. The values $\rho_\ell(v)$, and $B_\ell(v)$ are only changed when the pair (v, ℓ) is processed and then the invariant is trivially satisfied by the assignments in line 9 and line 11 of the algorithm. \square

Lemma 5.13. *After each iteration of the while loop in Algorithm GENBUCHIProgressMeasure for $v \in V_1$ we have*

$$C_\ell(v) = \begin{cases} |\{w \in \text{Out}(v) \mid \rho_{\ell \oplus 1}(w) < \infty\}| & \text{if } v \in T_\ell, \\ |\{w \in \text{Out}(v) \mid \rho_\ell(w) = B_\ell(v)\}| & \text{if } v \notin T_\ell, \rho_\ell(v) < \infty. \end{cases}$$

Proof. As *base case* consider the point where the algorithm first enters the while loop. All $\rho_\ell(v)$ and $B_\ell(v)$ are initialized to 0 and thus in both cases the right side of the invariant is equal to $Outdeg(v)$, which is exactly the value assigned to $C_\ell(v)$.

Now for the *induction step* consider an iteration of the loop and let us assume the Invariants (1)–(3) are satisfied before the loop. Let $v \in V_1$. In an iteration where (v, ℓ) is processed in line 10 we set $C_\ell(v)$ to $cnt_\ell(v)$ and hence the invariant is satisfied by the definition of $cnt_\ell(v)$. Otherwise the condition for $C_\ell(v)$ is only affected if a vertex $u \in Out(v)$ is processed. We distinguish the two cases where $v \in T_\ell$ and where $v \notin T_\ell$.

- If $v \in T_\ell$ then $C_\ell(v)$ is only affected in iterations where pairs $(u, \ell \oplus 1)$ are considered. If the updated value of $\rho_{\ell \oplus 1}(u)$ is less than ∞ then the set $\{w \in Out(v) \mid \rho_{\ell \oplus 1}(w) < \infty\}$ is unchanged and also $C_\ell(v)$ is not changed by the algorithm, i.e., the invariant is still satisfied. Otherwise if the updated value of $\rho_{\ell \oplus 1}(u)$ is ∞ then u drops out from the set $\{w \in Out(v) \mid \rho_{\ell \oplus 1}(w) < \infty\}$ but also the algorithm decreases $C_\ell(v)$ by one, i.e., again the invariant is satisfied.
- If $v \notin T_\ell$ and $\rho_\ell(v) < \infty$ then $C_\ell(v)$ is only affected in iterations where pairs (u, ℓ) are considered. Let $\rho_\ell^o(u)$ be the value of $\rho_\ell(u)$ before its update. If $\rho_\ell^o(u) > B_\ell(v)$ then $u \notin \{w \in Out(v) \mid \rho_\ell(w) = B_\ell(v)\}$ and thus the set is not affected by the increased value of $\rho_\ell(u)$. In that case the algorithm does not change $C_\ell(v)$ and thus the invariant is satisfied. Otherwise, if $\rho_\ell^o(u) = B_\ell(v)$, then $u \in \{w \in Out(v) \mid \rho_\ell(w) = B_\ell(v)\}$ before the iteration but not after the iteration. In that case the algorithm decreases $C_\ell(v)$ by one and thus the invariant is still satisfied.

Notice that by Invariants (1) and (2), it cannot happen that $\rho_\ell^o(u) < B_\ell(v)$. To see this, assume by contradiction $\rho_\ell^o(u) < B_\ell(v)$. Let $best_\ell^o(v)$ denote the value of $best_\ell(v)$ before the update of $\rho_\ell(u)$. By (1) we have $\rho_\ell(v) \leq incr_v^\ell(best_\ell^o(v))$, by the definition of $best_\ell^o(v)$ and $v \in V_1 \setminus T_\ell$ we have $best_\ell^o(v) \leq \rho_\ell^o(u)$ and thus by the assumption $best_\ell^o(v) < B_\ell(v)$. By (2) we have either $\rho_\ell(v) = incr_v^\ell(B_\ell(v))$ or $\rho_\ell(v) = 0$. In the first case, as $incr_v^\ell(x)$ is strictly increasing for $x < \infty$, we have $incr_v^\ell(best_\ell^o(v)) < incr_v^\ell(B_\ell(v)) = \rho_\ell(v)$ and thus a contradiction to (1). In the second case the pair (v, ℓ) was not processed yet and we have a contradiction by $B_\ell(v) = 0$. \square

Lemma 5.14. *After each iteration of the while loop in Algorithm GENBUCHI PROGRESS MEASURE we have that the set L consists exactly of the pairs (v, ℓ) with $\rho_\ell(v) < incr_v^\ell(best_\ell(v))$.*

Proof. The set L is initialized in line 5 with all pairs (v, ℓ) such that $v \notin T_\ell$. For all of these vertices we have $best_\ell(v) = 0$ and thus $incr_v^\ell(best_\ell(v)) = 1$, i.e., $\rho_\ell(v) = 0 < incr_v^\ell(best_\ell(v)) = 1$. Now consider $(v, \ell) \notin L$, i.e., $v \in T_\ell$. As all $\rho_\ell(v) = 0$, we have $incr_v^\ell(best_\ell(v)) = 0$ and thus $\rho_\ell(v) = 0 \not< incr_v^\ell(best_\ell(v)) = 0$. Hence, in the *base case* a pair (v, ℓ) is in L iff $\rho_\ell(v) = 0 < incr_v^\ell(best_\ell(v)) = 1$.

Now for the *induction step* consider an iteration of the loop and let us assume the Invariants (1)–(4) are satisfied before the loop. For the pair (v, ℓ) processed in the iteration $\rho_\ell(v)$ is set to $incr_v^\ell(best_\ell(v))$ and thus it can be removed from L . Notice that (a) the value of $\rho_\ell(w)$ is only changed when a pair (w, ℓ) is processed and (b) $incr_v^\ell(best_\ell(w))$ can only increase when other pairs (v, ℓ) are processed. Thus we have to show that in an iteration where the algorithm processes the pair (v, ℓ) all pairs (w, ℓ') with $\rho_{\ell'}(w) = incr_v^\ell(best_\ell(w))$ before the iteration and $\rho_{\ell'}(w) < incr_v^\ell(best_\ell(w))$ after the iteration are added to the set L . The only

vertices affected by the change of $\rho_\ell(v)$ are those in $In(v)$ which are either (i) not in T_ℓ or (ii) in $T_{\ell \oplus 1}$. In the former case only ρ_ℓ is affected while in the latter case only $\rho_{\ell \oplus 1}$ is affected. Let $\rho_\ell^o(v)$ and $\rho_\ell^n(v)$ be the values before, respectively after, the update on $\rho_\ell(v)$. Notice that if $w \notin T_\ell$ and $\rho_\ell(w) = 0$, then $(w, \ell) \in L$ by the initialization in line 5. Thus in the following, by Invariant (2), we can assume that $\rho_\ell(w) = \text{incr}_v^\ell(B_\ell(w))$ for all $(w, \ell) \notin L$. We consider the following cases.

- $w \in In(v) \setminus T_\ell$ and $w \in V_1$: Then $\text{incr}_v^\ell(\text{best}_\ell(w)) > \rho_\ell(w)$ iff all $u \in Out(w)$ have $\rho_\ell(u) > B_\ell(w)$. As $(w, \ell) \notin L$ we know that before the iteration there is at least one $u \in Out(w)$ with $\rho_\ell(u) = B_\ell(w)$. In the case $u \neq v$, $B_\ell(w)$ will not be changed during the iteration and thus $\text{incr}_v^\ell(\text{best}_\ell(w)) \not> \rho_\ell(w)$. Hence $\text{incr}_v^\ell(\text{best}_\ell(w)) > \rho_\ell(w)$ iff v is the only vertex in $Out(w)$ with $\rho_\ell^o(v) = B_\ell(w)$. But then, by Invariant (3), $C_\ell(v) = 1$ and thus the algorithm will reduce $C_\ell(v)$ to 0 and add (v, ℓ) to the set L in lines 14–15.
- $w \in In(v) \setminus T_\ell$ and $w \in V_2$: Then $\text{incr}_v^\ell(\text{best}_\ell(w)) > \rho_\ell(w)$ iff there is a vertex $u \in Out(w)$ with $\rho_\ell(u) > B_\ell(w)$. If there would be such an $u \in Out(w)$ different from v then by the induction hypothesis we already have $(v, \ell) \in L$. Thus we must have that $\rho_\ell^n(v) > B_\ell(w)$ and thus (w, ℓ) is added to L in line 16 of the algorithm.
- $w \in In(v) \cap T_{\ell \oplus 1}$ and $w \in V_1$: Then $\text{incr}_v^\ell(\text{best}_\ell(w)) > \rho_{\ell \oplus 1}(w)$ iff all $u \in Out(w)$ have $\rho_\ell(u) = \infty$ and $\rho_{\ell \oplus 1}(w) = 0$. This is the case iff v was the only vertex in $Out(w)$ with $\rho_\ell(v) < \infty$. But then, Invariant 3, $C_\ell(v) = 1$ and thus the algorithm will decrement $C_\ell(v)$ to 0 and add $(v, \ell \oplus 1)$ to the set L in lines 20–21.
- $w \in In(v) \cap T_{\ell \oplus 1}$ and $w \in V_2$: Then $\text{incr}_v^\ell(\text{best}_\ell(w)) > \rho_{\ell \oplus 1}(w)$ iff there is an $u \in Out(w)$ with $\rho_\ell(u) = \infty$ and $\rho_{\ell \oplus 1}(w) = 0$. If there would be such an $u \in Out(w)$ different from v then by the induction hypothesis we already have $(v, \ell \oplus 1) \in L$. Thus, we have that $\rho_\ell^n(v) = \infty > \rho_{\ell \oplus 1}(w)$ and $\text{incr}_v^\ell(\rho_\ell^n(v)) = \infty > \rho_{\ell \oplus 1}(w) = 0$. In that case $(w, \ell \oplus 1)$ is added to L in line 22 of the algorithm. \square

Lemma 5.15. *For each player-1 dominion D with $|D| \leq h$, for each $v \in D$, and all $1 \leq \ell \leq k$ we have $\rho_\ell(v) \leq \text{rank}_1(\mathcal{G}, T_\ell \cap D, v) < h$.*

Proof. As all functions $\rho_\ell(\cdot)$ are initialized with the 0-function, the invariant is satisfied trivially in the *base case* when the algorithm first enters the while loop.

Now for the *induction step* consider an iteration of the loop and let us assume all the invariants are satisfied before the loop. First, notice that as $|D| \leq h$, we have $\text{rank}_1(\mathcal{G}, T_\ell \cap D, v) < h$ for all $1 \leq \ell \leq k$ and $v \in D$. The value $\rho_\ell(v)$ is only updated in line 11 and there set to $\text{incr}_v^\ell(\text{best}_\ell(v))$. We distinguish three different cases.

- Assume $v \in V_1$ and $\text{rank}_1(\mathcal{G}, T_\ell \cap D, v) = j$ with $1 \leq j < h$ then, by definition of rank_1 , there is a $w \in D, w \neq v$, with $(v, w) \in E$ and $\text{rank}_1(\mathcal{G}, T_\ell \cap D, w) = j - 1$. Now as the invariant is valid before the iteration and $\rho_\ell(w)$ is not changed during the iteration, we have $\rho_\ell(w) \leq j - 1$ and thus $\text{best}_\ell(v) \leq j - 1$. Hence, $\text{incr}_v^\ell(\text{best}_\ell(v)) \leq j$ and the invariant is still satisfied.
- Assume $v \in V_2$ and $\text{rank}_1(\mathcal{G}, T_\ell \cap D, v) = j$ with $1 \leq j < h$ then, by definition of rank_1 , $\text{rank}_1(\mathcal{G}, T_\ell \cap D, w) = j - 1$ for each $(v, w) \in E$ (as D is 2-closed we have $w \in D$). Now as the invariant is valid before the iteration and $\rho_\ell(w)$ is not changed during the

iteration, we have $\rho_\ell(w) \leq j - 1$ for each $(v, w) \in E$ and thus $\text{best}_\ell(v) \leq j - 1$. Hence, $\text{incr}_v^\ell(\text{best}_\ell(v)) \leq j$ and the invariant is still satisfied.

- Finally, assume $\text{rank}_1(\mathcal{G}, T_\ell \cap D, v) = 0$, that is $v \in T_\ell$. By the induction hypothesis for all $w \in D$ with $(v, w) \in E$ it holds that $\rho_{\ell \oplus 1}(w) < h$ (and there exists such a $w \in D$) and thus $\text{best}_\ell(v) < h$. Hence, $\text{incr}_v^\ell(\text{best}_\ell(v)) = 0$ and the loop invariant is still satisfied.

Hence, this loop invariant is maintained during the whole algorithm. \square

So far we have shown that the algorithm behaves as described by Invariant 5.10. The next lemma provides the ingredients to show that the set $W = \{v \in V \mid \rho_\ell(v) < \infty \text{ for some } \ell\}$ is a player-1 dominion by exploiting the fact that the functions ρ_ℓ form a fixed-point of the update operator.

Lemma 5.16. *Let $W = \{v \in V \mid \rho_\ell(v) < \infty \text{ for some } \ell\}$ be the set computed by Algorithm GENBUCHI PROGRESS MEASURE.*

- (1) *For all $v \in V$: If $\rho_\ell(v) < \infty$, then player 1 has a strategy to reach $\{v' \in T_\ell \mid \rho_\ell(v') = 0\}$ from v by only visiting vertices in W .*
- (2) *For all $v \in T_\ell$: If $\rho_\ell(v) = 0$, then player 1 has a strategy to reach $\{v' \in T_{\ell \oplus 1} \mid \rho_{\ell \oplus 1}(v') = 0\}$ from v by only visiting vertices in W .*

Proof. Notice that by the Invariants (1) & (4) we have $\rho_\ell(v) = \text{incr}_v^\ell(\text{best}_\ell(v))$ for all $v \in V$ and all $1 \leq \ell \leq k$, i.e., the functions $\rho_\ell(v)$ are a fixed-point for the $\text{incr}_v^\ell(\text{best}_\ell(v))$ updates.

(1) Consider a vertex $v \in V$ with $\rho_\ell(v) = j$ for $0 < j < h$. We will show by induction in j that then player 1 has a strategy to reach $S = \{v' \in T_\ell \mid \rho_\ell(v') = 0\}$ from v by only visiting vertices in W . For the *base case* we exploit that the functions $\rho_\ell(v)$ are a fixed-point of the $\text{incr}_v^\ell(\text{best}_\ell(v))$ updates. By the definition of incr_v^ℓ we have that $\rho_\ell(v) = 0$ only if $v \in T_\ell$ ³ and thus we already have reached S in the base case.

For the *induction step* let us assume the claim holds for all $j' < j$ and consider a vertex v with $\rho_\ell(v) = j$. We distinguish the cases $v \in V_1$ and $v \in V_2$.

- $v \in V_1$: Since ρ is a fixed-point of $\text{incr}_v^\ell(\text{best}_\ell(v))$, we have that there is at least one vertex w with $(v, w) \in E$ and $\rho_\ell(w) = j - 1$. By the induction hypothesis, player 1 has a strategy to reach S starting from w , and, as player 1 can choose the edge (v, w) , also a strategy starting from v .
- $v \in V_2$: Since ρ is a fixed-point of $\text{incr}_v^\ell(\text{best}_\ell(v))$, we have that $\rho_\ell(w) < j$ for all vertices w with $(v, w) \in E$. By the induction hypothesis player 1 has a strategy to reach S starting from any w with $(v, w) \in E$, and thus also when starting from v .

Moreover, in both cases only the vertex v is added to the path induced by the strategy, which by definition is in W . Hence, in both cases player 1 has a strategy to reach S from v by only visiting vertices in W , which concludes the proof of part 1.

(2) Recall that we have $v \in T_\ell$ and $\rho_\ell(v) = 0$. Let $S' = \{v' \in T_{\ell \oplus 1} \mid \rho_{\ell \oplus 1}(v') = 0\}$. Again we distinguish whether $v \in V_1$ or $v \in V_2$.

³Recall that we assume that each vertex has at least one outgoing edge.

- If $v \in V_1$, then, as the functions ρ_ℓ form a fixed-point, there is at least one vertex w with $(v, w) \in E$ and $\rho_{\ell \oplus 1}(w) < \infty$. Then by (1) player 1 has a strategy to reach S' starting from w , and, as player 1 can choose the edge (v, w) , also a strategy starting from v .
- If $v \in V_2$, then, as ρ is a fixed-point, we have $\rho_{\ell \oplus 1}(w) < \infty$ for all w with $(v, w) \in E$. Then by (1) player 1 has a strategy to reach S' starting from any w with $(v, w) \in E$, and thus also when starting from v .

Again, in both cases only the vertex v is added to the path induced by the strategy, which by definition is in W , and thus in both cases player 1 has a strategy to reach S' , which concludes the proof of part 2. \square

We are now prepared to prove the correctness of Algorithm **GENBUCHI PROGRESS MEASURE**.

Proposition 5.17. *For the game graph \mathcal{G} and objective $\bigwedge_{1 \leq \ell \leq k} \text{Büchi}(T_\ell)$, Algorithm **GENBUCHI PROGRESS MEASURE** either returns a player-1 dominion or the empty set, and, if there is at least one player-1 dominion of size $\leq h$ then it returns a player-1 dominion containing all player-1 dominions of size $\leq h$.*

Proof. We will show that (1) $W = \{v \in V \mid \rho_\ell(v) < \infty \text{ for some } \ell\}$ is a player-1 dominion and that (2) each player-1 dominion of size $\leq h$ is contained in W .

(1) The following strategy is winning for player 1 and does not leave W . First, for vertices $v \in W \setminus \bigcup_{\ell=1}^k T_\ell$ pick some ℓ s.t. $\rho_\ell(v) < \infty$ and play the strategy given by Lemma 5.16(1) to reach $U_\ell \cap W$. The first time a set U_ℓ is reached, start playing the strategies given by Lemma 5.16(2) to first reach the set $U_{\ell \oplus 1} \cap W$, then the set $U_{\ell \oplus 2} \cap W$ and so on. This strategy visits all Büchi sets infinitely often and will never leave the set W . That is, W is a player-1 dominion.

(2) Consider a player-1 dominion D with $|D| \leq h$. Then, we have that $\text{rank}_1(\mathcal{G}, T_\ell \cap D, v) \leq h - 1$ for all T_ℓ and all $v \in D$ and by Invariant (5) that $\rho_\ell(v) \leq h - 1$ for all $v \in D$. That is, each $d \in D$ has $\rho_1(v) < \infty$ and thus $D \subseteq W$. \square

Finally, let us consider the runtime of Algorithm **GENBUCHI PROGRESS MEASURE**.

Proposition 5.18. *Algorithm **GENBUCHI PROGRESS MEASURE** runs in time $O(k \cdot h \cdot m)$.*

Proof. Notice that the functions $\text{best}_\ell(v)$ and $\text{cnt}_\ell(v)$ can be computed in time $O(\text{Outdeg}(v))$ while $\text{incr}_v^\ell(\cdot)$ is in constant time. An iteration of the initial foreach loop takes time $O(\text{Outdeg}(v))$ and, as each $v \in V$ is considered k times, the entire foreach loop takes time $O(k \cdot m)$. The running time of Algorithm **GENBUCHI PROGRESS MEASURE** is dominated by the while loop. Processing a pair $(v, \ell) \in L$ takes time $O(\text{Outdeg}(v) + \text{Indeg}(v))$. Moreover, whenever (v, ℓ) is processed, the value of $\rho_\ell(v)$ is increased by 1 if $v \notin T_\ell$ or by ∞ if $v \in T_\ell$ and thus each pair can be considered at most h times. Hence, for the entire while loop we have a running time of $O\left(h \cdot \sum_{\ell=1}^k \sum_{v \in V} (\text{Outdeg}(v) + \text{Indeg}(v))\right)$ which can be simplified to $O(k \cdot h \cdot m)$. \square

5.3 Our Improved Algorithm for GR(1) Games

In this section we present our $O(k_1 k_2 \cdot n^{2.5})$ -time algorithm for GR(1) games, see Algorithm **GR(1)GAME**. The overall structure of the algorithm is the same as for the basic algorithm: We search for a player-2 dominion S^j and if one is found, then its player-2 attractor D^j is determined and removed from the current game graph \mathcal{G}^j (with $\mathcal{G}^1 = \mathcal{G}$) to create the game graph for the next iteration, \mathcal{G}^{j+1} . If no player-2 dominion exists, then the remaining vertices are returned as the winning set of player 1. The difference to the basic algorithm lies in the way we search for player-2 dominions. Two different procedures are used for this purpose: First we search for “small” dominions with the subroutine **kGenBüchiDominion**. If no small dominion exists, then we search for player-2 dominions as in the basic algorithm. The guarantee that we find a “large” dominion in the second case (if a player-2 dominion exists) allows us to bound the number of times this can happen. The subroutine **kGenBüchiDominion** called with parameter h_{\max} on a game graph \mathcal{G} provides the guarantee to identify all player-2 dominions D for which $|Attr_2(\mathcal{G}, D)| \leq h_{\max}$, where h_{\max} is set to \sqrt{n} to achieve the desired runtime.

Search for Large Dominions. If the subroutine **kGenBüchiDominion** returns an empty set, i.e., when we have for all player-2 dominions D that $|Attr_2(\mathcal{G}^j, D)| > h_{\max}$, then we search for player-2 dominions as in the basic algorithm: For each $1 \leq \ell \leq k_2$ first the player-1 attractor Y_ℓ^j of U_ℓ^j is temporarily removed from the graph. Then a generalized Büchi game with target sets $L_1^j \setminus Y_\ell^j, \dots, L_{k_1}^j \setminus Y_\ell^j$ is solved on $\mathcal{G}^j \setminus Y_\ell^j$. The generalized Büchi player in this game corresponds to player 2 in the GR(1) game and his winning set to a player-2 dominion in the GR(1) game, see Lemma 5.2.

Procedure kGenBüchiDominion. The procedure **kGenBüchiDominion** searches for player-2 dominions in the GR(1) game, and returns some dominion if there exists a dominion D with $|Attr_2(\mathcal{G}, D)| \leq h_{\max}$. To this end we again consider generalized Büchi games with target sets $L_1^j, \dots, L_{k_1}^j$, where the generalized Büchi player corresponds to player 2 in the GR(1) game. We use the same hierarchical graph decomposition as for Algorithm **GENBUCHIGAME**: Let the incoming edges of each vertex be ordered such that the edges from vertices of V_2 come first; for a given game graph \mathcal{G}^j the graph G_i^j contains all vertices of \mathcal{G}^j , for each vertex its first 2^i incoming edges, and for each vertex with outdegree at most 2^i all its outgoing edges. The set Z_i^j contains all vertices of V_1 with outdegree larger than 2^i in \mathcal{G}^j and all vertices of V_2 that have no outgoing edge in G_i^j . We start with $i = 1$ and increase i by one as long as no dominion was found. For a given i we perform the following operations for each $1 \leq \ell \leq k_2$: First the player 1 attractor $Y_{i,\ell}^j$ of $U_\ell^j \cup Z_i^j$ is determined. Then we search for player-1 dominions on $\mathcal{G}_i^j \setminus Y_{i,\ell}^j$ w.r.t. the objective $\bigwedge_{t=1}^{k_1} \text{Büchi} \left(L_t \setminus Y_{i,\ell}^j \right)$ with the generalized Büchi progress measure algorithm and parameter $h = 2^i$, i.e., by Theorem 5.8 the progress measure algorithm returns all generalized Büchi dominions in $\mathcal{G}_i^j \setminus Y_{i,\ell}^j$ of size at most h .

The following lemma shows how the properties of the hierarchical graph decomposition extend from generalized Büchi games to GR(1) games. The first part is crucial for correctness: Every non-empty set found by the progress measure algorithm on $\mathcal{G}_i^j \setminus Y_{i,\ell}^j$ for some i and ℓ is indeed a player-2 dominion in the GR(1) game. The second part is crucial for the runtime argument: Whenever the basic algorithm for GR(1) games would identify a player-2

Algorithm GR(1)GAME: GR(1) Games in $O(k_1 \cdot k_2 \cdot n^{2.5})$ Time

Input : Game graph $\mathcal{G} = ((V, E), (V_1, V_2))$, Obj. $\bigwedge_{t=1}^{k_1} \text{Büchi}(L_t) \rightarrow \bigwedge_{\ell=1}^{k_2} \text{Büchi}(U_\ell)$
Output: Winning set of player 1

dominion D with $|\text{Attr}_2(\mathcal{G}, D)| \leq 2^i$, then D is also a generalized Büchi dominion in $\overline{\mathcal{G}_i^j \setminus Y_{i,\ell}^j}$ for some ℓ .

Lemma 5.19. *Let the notation be as in Algorithm GR(1)GAME.*

1. Every $X_{i,\ell}^j \neq \emptyset$ is a player-2 dominion in the GR(1) game on \mathcal{G}^j with $X_{i,\ell}^j \cap U_\ell^j = \emptyset$.
2. If for player 2 there exists in \mathcal{G}^j a dominion D w.r.t. the generalized Büchi objective $\bigwedge_{t=1}^{k_1} \text{Büchi}(L_t^j)$ such that $D \cap U_\ell^j = \emptyset$ for some $1 \leq \ell \leq k_2$ and $|\text{Attr}_2(\mathcal{G}^j, D)| \leq 2^i$, then D is a dominion w.r.t. the generalized Büchi objective $\bigwedge_{t=1}^{k_1} \text{Büchi}(L_t^j \setminus Y_{i,\ell}^j)$ in $\mathcal{G}_i^j \setminus Y_{i,\ell}^j$.

Proof. We prove the two points separately.

1. By Theorem 5.8 the set $X_{i,\ell}^j$ is a player-2 dominion on $\mathcal{G}_i^j \setminus Y_{i,\ell}^j$ w.r.t. the generalized Büchi objective $\bigwedge_{t=1}^{k_1} \text{Büchi}(L_t^j \setminus Y_{i,\ell}^j)$ of player 2. By Lemma 2.2(3) $V^j \setminus Y_{i,\ell}^j$ is closed for player 1 on \mathcal{G}_i^j . Thus by Lemma 2.2(4) $X_{i,\ell}^j$ is a player-2 dominion w.r.t. the generalized Büchi objective also in \mathcal{G}_i^j . As $X_{i,\ell}^j$ is player 1 closed in \mathcal{G}_i^j and does not intersect with Z_i^j , it is player 1 closed in \mathcal{G}^j by Lemma 3.4(1). Thus by $E_i^j \subseteq E^j$, the set $X_{i,\ell}^j$ is a player-2 dominion w.r.t. the generalized Büchi objective also in \mathcal{G}^j . Since $X_{i,\ell}^j$ does not intersect with U_ℓ^j , it is also a player-2 dominion in the GR(1) game on \mathcal{G}^j (cf. Lemma 5.2).
2. Since every player-2 dominion is player-1 closed, we have by Lemma 3.4(2) that (i) $\mathcal{G}^j[D] = \mathcal{G}_i^j[D]$, (ii) D does not intersect with Z_i^j , and (iii) D is player 1 closed in \mathcal{G}_i^j . Thus we have that (a) D does not intersect with $Y_{i,\ell}^j$ and (b) player 2 can play the same winning strategy for the vertices in D on \mathcal{G}_i^j as on \mathcal{G}^j . \square

From this we can draw the following two corollaries: (1) When we had to go up to i^* in the graph decomposition to find a dominion, then its attractor has size at least 2^{i^*-1} and (2) when `kGenBüchiDominion` returns an empty set, then all player-2 dominions in the current game graph have more than $h_{\max} = \sqrt{n}$ vertices.

Corollary 5.20. *Let j be some iteration of the repeat-until loop in Algorithm GR(1)GAME and consider the call to `kGenBüchiDominion`($\mathcal{G}^j, \{U_\ell^j\}, \{L_t^j\}, h_{\max}$).*

1. *If for some $i > 1$ we have $X_{i,\ell}^j \neq \emptyset$ but $X_{i-1,\ell}^j = \emptyset$, then $|\text{Attr}_2(\mathcal{G}^j, X_{i,\ell}^j)| > 2^{i-1}$.*
2. *If `kGenBüchiDominion`($\mathcal{G}^j, \{U_\ell^j\}, \{L_t^j\}, h_{\max}$) returns the empty set, then for every player-2 dominion D in the GR(1) game we have $|\text{Attr}_2(\mathcal{G}^j, D)| > h_{\max}$.*

Proof. We prove the two points separately.

1. By Lemma 5.19(1) $X_{i,\ell}^j$ is a player-2 dominion in the GR(1) game on \mathcal{G}^j with $X_{i,\ell}^j \cap U_\ell^j = \emptyset$ and thus in particular a dominion w.r.t. the generalized Büchi objective $\bigwedge_{t=1}^{k_1} \text{Büchi}(L_t^j)$ such that $X_{i,\ell}^j \cap U_\ell^j = \emptyset$. Assume by contradiction $|\text{Attr}_2(\mathcal{G}^j, X_{i,\ell}^j)| \leq 2^{i-1}$. Then by Lemma 5.19(2) we have $X_{i-1,\ell}^j \neq \emptyset$, a contradiction.
2. Assume there exists a 2-dominion D with $|\text{Attr}_2(\mathcal{G}^j, D)| \leq h_{\max}$. Then by Lemma 5.3 there is also a 2-dominion $D' \subseteq D$ that meets the criteria of Lemma 5.19(2). Let i' be the minimal value such that $|\text{Attr}_2(\mathcal{G}^j, D')| \leq 2^{i'}$, certainly $i' \leq \lceil \log_2(h_{\max}) \rceil$. Now, by Lemma 5.19(2), we have that D' is a dominion w.r.t. the generalized Büchi objective $\bigwedge_{t=1}^{k_1} \text{Büchi}(L_t^j \setminus Y_{i',\ell}^j)$ in $\mathcal{G}_{i'}^j \setminus Y_{i',\ell}^j$. By the correctness of Algorithm GENBÜCHIPROGRESSMEASURE, the set $X_{i',\ell}^j$ is a dominion containing D' and thus `kGenBüchiDominion`($\mathcal{G}^j = ((V^j, E^j), (V_1^j, V_2^j)), \{U_\ell^j\}, \{L_t^j\}, h_{\max}$) returns a non-empty set. \square

For the final game graph \mathcal{G}^{j^*} we can build a winning strategy for player 1 in the same way as for Algorithm **GR(1)GAMEBASIC**. That is, by combining her winning strategies for the disjunctive objective in the subgraphs $\overline{\mathcal{G}_\ell^{j^*}}$ and the attractor strategies for $\text{Attr}_1(\mathcal{G}^{j^*}, U_\ell)$.

Lemma 5.21 (Soundness of Algorithm **GR(1)GAME**). *Let V^{j^*} be the set of vertices returned by Algorithm **GR(1)GAME**. Each vertex in V^{j^*} is winning for player 1.*

Proof. When the algorithm terminates we have $S^{j^*} = \emptyset$. Thus the winning strategy of player 1 can be constructed in the same way as for the set returned by Algorithm **GR(1)GAMEBASIC**. (cf. Proof of Proposition 5.4) \square

Next we show that whenever Algorithm **GR(1)GAME** removes vertices from the game graph, these vertices are indeed winning for player 2. This is due to Lemma 5.19(1), stating that these sets are 2-dominions in the current game graph and Lemma 2.2, stating that all player-2 dominions of the current game graph \mathcal{G}^j are also winning for player 2 in the original game graph \mathcal{G} .

Lemma 5.22 (Completeness Algorithm **GR(1)GAME**). *Let V^{j^*} be the set of vertices returned by Algorithm **GR(1)GAME**. Each vertex in $V \setminus V^{j^*}$ is winning for player 2.*

Proof. By Lemma 2.2(5) it is sufficient to show that in each iteration j with $S^j \neq \emptyset$ player 2 has a winning strategy from the vertices in S^j in \mathcal{G}^j . If a non-empty set S^j is returned by **kGenBüchiDominion**, then S^j is winning for player 2 by Lemma 5.19(1). For the case where S^j is empty after the call to **kGenBüchiDominion**, the set S^j is determined in the same way as in the basic algorithm for GR(1) games and thus is winning by the correctness of Algorithm **GR(1)GAMEBASIC** (cf. Proof of Proposition 5.5). \square

Finally, as the runtime of the subroutine **kGenBüchiDominion** scales with the size of the smallest player-2 dominion in \mathcal{G}^j and we have only make $O(\sqrt{n})$ many calls to **GenBüchiGame**, we obtain a runtime of $O(k_1 \cdot k_2 \cdot n^{2.5})$.

Theorem 5.23 (Runtime Algorithm **GR(1)GAME**). *The algorithm can be implemented to terminate in $O(k_1 \cdot k_2 \cdot n^{2.5})$ time.*

Proof. We analyze the *total* runtime over all iterations of the repeat-until loop. The analysis uses that whenever a player-2 dominion D^j is identified, then the vertices of D^j are removed from the maintained game graph. In particular, we have that whenever **kGenBüchiDominion** returns an empty set, either at least $h_{\max} = \sqrt{n}$ vertices are removed from the game graph or the algorithm terminates. Thus this case can happen at most $O(n/h_{\max}) = O(\sqrt{n})$ times. In this case **GenBüchiGame** is called k_2 times. By Proposition 3.8 this takes total time $O(\sqrt{n} \cdot k_2 \cdot k_1 \cdot n^2) = O(k_1 k_2 \cdot n^{2.5})$.

We next bound the total time spent in **kGenBüchiDominion**. To efficiently construct the graphs G_i^j and the vertex sets Z_i^j we maintain (sorted) lists of the incoming and the outgoing edges of each vertex. These lists can be updated whenever an obsolete entry is encountered in the construction of G_i^j ; as each entry is removed at most once, maintaining this data structures takes total time $O(m)$. Now consider a fixed iteration i of the outer for-loop in **kGenBüchiDominion**. The graph G_i^j has $O(2^i \cdot n)$ edges and thus, given the

above data structure for adjacent edges, the graphs G_i^j and the sets Z_i^j can be constructed in $O(2^i \cdot n)$ time. Further the k_2 attractor computations in the inner for-loop can be done in time $O(k_2 \cdot 2^i \cdot n)$. The runtime of iteration i is dominated by the k_2 calls to **GenBüchiProgressMeasure**. By Theorem 5.8 the calls to **GenBüchiProgressMeasure** in iteration i , with parameter h set to 2^i , take time $O(k_1 k_2 \cdot n \cdot 2^{2i})$. Let i^* be the iteration at which **kGenBüchiDominion** stops after it is called in the j th iteration of the repeat-until loop. The runtime for this call to **kGenBüchiDominion** from $i = 1$ to i^* forms a geometric series that is bounded by $O(k_1 k_2 \cdot n \cdot 2^{2i^*})$. By Corollary 5.20 either (1) a dominion D with $|Attr_2(\mathcal{G}^j, D)| > 2^{i^*-1}$ vertices was found by **kGenBüchiDominion** or (2) all dominions in \mathcal{G}^j have more than h_{\max} vertices. Thus either (2a) a dominion D with more than h_{\max} vertices is detected in the subsequent call to **GenBüchiGame** or (2b) there is no dominion in \mathcal{G}^j and j is the last iteration of the algorithm. Case (2b) can happen at most once and its runtime is bounded by $O(k_1 k_2 \cdot n \cdot 2^{2 \log(h_{\max})}) = O(k_1 k_2 \cdot n^2)$. In the cases (1) and (2a) more than 2^{i^*-1} vertices are removed from the graph in this iteration, as $h_{\max} > 2^{i^*-1}$. We charge each such vertex $O(k_1 k_2 \cdot n \cdot 2^{i^*}) = O(k_1 k_2 \cdot n \cdot h_{\max})$ time. Hence the total runtime for these cases is $O(k_1 k_2 \cdot n^2 \cdot h_{\max}) = O(k_1 k_2 \cdot n^{2.5})$. \square

Remark 5.24. Algorithm **GR(1)GAME** can be modified to additionally return winning strategies for both players. Procedure **GenBüchiProgressMeasure**(\mathcal{G}, ψ, h) can be modified to return a winning strategy within the returned dominion. Procedure **GenBüchiGame** can be modified to return winning strategies for both player in the generalized Büchi game. Thus for player 2 a winning strategy for the dominion D^j that is identified in iteration j of the algorithm can be constructed by combining his winning strategy in the generalized Büchi game in which S^j was identified with his attractor strategy to the set S^j . For player 1 we can obtain a winning strategy in the final iteration of the algorithm by combining for $1 \leq \ell \leq k_2$ her attractor strategies to the sets \underline{U}_ℓ with her winning strategies in the generalized Büchi games for each of the game graphs $\mathcal{G}_i^j \setminus Y_{i,\ell}^j$ (as described in the proof of Proposition 5.4).

6 Conclusion

In this work we consider the algorithmic problem of computing the winning sets for games on graphs with generalized Büchi and GR(1) objectives. We present improved algorithms for both, and conditional lower bounds for generalized Büchi objectives.

The existing upper bounds and our conditional lower bounds are tight for (a) for dense graphs, and (b) sparse graphs with constant size target sets. Two interesting open questions are as follows: (1) For sparse graphs with $\theta(n)$ many target sets of size $\theta(n)$ the upper bounds are cubic, whereas the conditional lower bound is quadratic, and closing the gap is an interesting open question. (2) For GR(1) objectives we obtain the conditional lower bounds from generalized Büchi objectives, which are not tight in this case; whether better (conditional) lower bounds can be established also remains open.
